Air pollutants are generally classified as particulates and gases. The *particulates* include dusts which may be both naturally occurring and man-made: fumes, smoke and mist. Dust particles may be chemically classified as carbonaceous, containing combustible carbon; silicious, having free silica or silicates in the compound, or of a specific chemical composition such as cement dust.

The most common *gaseous air pollutants* are the sulfur gases including sulfur dioxide, hydrogen sulfide, a series of thiols and mercaptans; the nitrogen gases consisting mainly of oxides of nitrogen and ammonia, ozone, carbon monoxide, and a long list of hydrocarbons and their derivatives. The polycyclic hydrocarbons have been studied intensively as air pollutants mainly because some of them are suspected of being carcinogenic.

Toxicity

The toxic effect of a mixture of the different air contaminants is quite complicated; therefore it is not reasonable to consider each specific contaminant by itself. The synergistic actions of mixtures of different materials have not been evaluated in most cases. The problem is further complicated by the fact that each air pollutant may be present in varying amounts and the question of absorption of gases into liquids or adsorption on solid particles must be considered as well as the reaction of gases with other gases or particulate matter. The entire field of toxicology of air pollutants needs much further study.

Acute Exposure

Effects on human health of exposure to air contamination must be considered for either acute or severe exposures to relatively high concentrations of pollutants for a relatively short period of time or mild or chronic exposures to long periods of community air pollution. Throughout the world in the past three decades there have been several similar examples of acute exposures with definite effects on human health.

Weather and Temperature Inversions

In December 1930 an air pollution disaster occurred along the Meuse River Valley in Belgium.[1] A heavily industrialized area with numerous small communities was subjected to about one week of heavy weather including a continuous temperature inversion. A total of 63 persons died following this severe exposure and several thousand others were said to be ill. A serious episode occurred in October 1948 in Donora, Pennsylvania, with similar results.[2] A valley community, Donora, with a population of about 12,000, was subjected to four and a half days of stable weather conditions. There were twenty deaths, but more significantly it was found that about 50% of the citizens became ill from this exposure.

In November 1950 an industrial accident involving a flare used to control the release of hydrogen sulfide from an oil refinery operation caused the death of 22 persons in Poza Rica, Mexico.[3] At the time of the episode a temperature inversion was present over the valley community. In Poza Rica it was found that those who died included persons of different ages and states of health. In Belgium and Donora older persons with certain health impairments succumbed to the acute exposure.

The air pollution disaster with the greatest death total occurred in December 1952 in London, England, when about 4,000 deaths were attributed to a week-long smog period.[4] Again a temperature inversion along with stable weather conditions held the air pollutants close to the ground and the entire population was exposed. In this episode the normal death rates were greatly increased for older persons and also for infants under one year of age. Concentrations of sulfur dioxide in areas where the highest death rate was noted amounted to 0.6 part per million or less. This is not considered to be a hazardous exposure for humans and indicates that there must be a combined effect of different pollutants.

Community Exposure

The health effects from community exposure may result from a lifetime of living in an atmosphere with varying amounts of pollution. The Los Angeles smog is an oxidizing type of pollution primarily because ozone and other oxidizing substances are present in the air. The health effects from this type of pollution would undoubtedly be different from the reducing atmosphere with quantities of soot and sulfur dioxide as found in New York City, Chicago, Pittsburgh and most Midwest cities.

Most of the health effects are involved with the lungs and there is evidence to show a direct link between community air pollution and lung cancer, bronchitis, emphysema and asthma.

Of special interest to this group should be two recent studies on the health effects of children related to community pollution. Gol'dberg[6] reported on a study of Russian school children from eight to 12 years of age who were exposed periodically to emissions from a power plant located a few miles away from the school yard,[6] from which an average of 800 tons of fly ash and 350 tons of sulfur dioxide were dissipated daily throughout the atmosphere. It was found that 20% of the chest x-rays of these children resembled borderline silicosis. A later study was made on the same children after the contamination was removed and recovery was noted in some of the x-rays.

Another study[7] of[4] 3860 children in Britain for the first five years of their life and a reexamination of their lungs at ages six, 11, and 15, correlating the findings of the physical examinations with the smoke and sulfur dioxide indices, revealed that the upper respiratory infections were not related, but the lower respiratory infections were related, to community air pollution exposures.

Current Research

Studies on the pulmonary tissue reactions to ozone, oxides of nitrogen, sulfur dioxide, various hydrocarbons and synthetic smog, using nine different kinds of animals with varying concentrations and periods of exposure, have justified the following general conclusions:

1. Definite morphological and functional changes in lung tissue have been observed only when the concentrations are several times higher than those found in the atmosphere.
2. Tolerance to a given pollutant is developed by the animal exposed. To this end, animals exposed to low concentrations of ozone were later able to withstand supposedly lethal doses.
3. Exposure to certain gases increases animal susceptibility to bacterial infections.
4. The role of particulates along with gases in lung tissue reactions appears to be quite important.

Ozone

Sufficient evidence is available to show that acute exposures of ozone are highly toxic, yet reports of the morphological changes associated with ozone toxicity are relatively few. Microscopical investigations have been made using concentrations of ozone ranging from 0.2 to 50 ppm on mice, rats, hamsters, rabbits, and dogs. Methods of exposure varied from single doses for one to six hours, to multiple or continuous doses for up to 433 days. Morphological changes seen with the light microscope after a single dose are accumulation of edema fluid and migration of leucocytes into the alveolar space. Electron microscopy has revealed swelling and rupture of endothelial and epithelial cells and accumulation of cell debris in the alveoli. In prolonged studies chronic pneumonitis and contracted alveolar septa are seen.[8]

Nitrogen Dioxide

The effects of nitrogen dioxide on mammals are seen mostly in the respiratory tract. Experimental exposures as high as 400 ppm cause bronchopneumonia and death within minutes in laboratory animals. At 40-80 ppm severe ultrastructural alterations were seen in middle-aged mice exposed to NO_2 for about one hour. The same age animals exposed for 24 hours at 25 ppm showed slight damage to lung lining membranes. Very slight histopathology is evident with levels in the 0.5-5 ppm range continuously for 12 months or more.[8]

Other gaseous air pollutants have been studied even less for their histopathologic effects. Sulfur dioxide produces little or no morphologic change in lungs even with daily exposures of 25-50 ppm for a month. Severe ultrastructural damage to the lungs has been reported after 15-30 minutes of 0.5-1.0% carbon monoxide. Exposures of 700 ppm carbon monoxide for four hours have produced swelling of capillary lining cells and excess cell debris in capillaries of dog and mouse lungs. Tissue effects of pollutant mixtures are scarce and add more parameters to the already complicated literature.[8]

Conclusions

The disasters in Belgium, Donora, Mexico and London leave no doubt as to the effect on human health of acute exposures to air pollutants. However, there is considerable uncertainty about the effect of community exposures of large groups of people. The problem is a very complicated one and it will be difficult to develop conclusive proof on specific effects. Research on toxicology and pulmonary tissue reactions to different air pollutants is now under way.

Eventually it may be learned that human health effects from exposures to air pollutants could be quite pronounced. There is no doubt but that the concentrations of air pollutants have been steadily increasing and that more and more people are being exposed.

Hamman-Rich Syndrome*

This syndrome is characterized by a generalized progressive pulmonary fibrosis of unknown etiology. The condition was first described in 1935 by Hamman and Rich who elaborated upon the subject in 1944. Approximately 41 cases have been reported. The syndrome is probably more frequently observed than the number of reported cases would indicate. It occurs most often between 40 and 50 years of age. Genetic and familial factors have not been emphasized, but there have been a few instances of occurrence in siblings.

The onset of symptoms is insidious. There is easy fatigability, weight loss, and intermittent or progressive dyspnea and cough. Pulmonary roentgenograms show a diffuse mottling. Eventually, clubbing of the fingers and toes and right-sided heart failure with cor pulmonale may supervene.

No specific bacteria have been isolated; the etiologic agent is considered most likely to be a virus. Diagnosis can best be established by pulmonary biopsy. Pathologic studies reveal an unusual inflammatory reaction with eosinophilic infiltration, absence of stainable bacteria, interstitial fibrosis, a diffuse collagenous hyperplasia in the interstitial peribronchial and perivascular areas, enlargement of the epithelial cells that line the alveoli, and necrosis of both bronchiolar and alveolar epithelium. Attention has been called to the similarity of the pulmonary pathology and a localized scleroderma of the lung. The syndrome may eventually be proved to be related to the collagen group of disorders.

The clinical course is characterized by irregular exacerbations. It may run a fulminating course of only a few weeks or continue for a few years. Sooner or later interruption of the alveolar oxygen exchange becomes progressive and respiratory and cardiac insufficiencies ensue. The therapeutic use of cortisone not infrequently affords temporary symptomatic relief, and there is roentgenographic evidence of some clearing of the pulmonary infiltration. It should be recognized, however, that the sudden discontinuance of cortisone therapy may result in a rapidly fatal outcome.

Cigarette Smoking and Chronic Respiratory Disease*

NORMAN G. G. HEPPER, M.D.†
Rochester, Minnesota

MOST OF THE EPIDEMIOLOGIC and clinical studies of the relationship between cigarette smoking and chronic respiratory disease have focused on chronic bronchitis and chronic obstructive lung disease in the adult population. Cigarette smoking is less of a problem in chronic respiratory disease of children; however, it is reasonable to assume that the effects of cigarette smoke on the lungs will occur at whatever age the smoker may be. Hence all physicians who care for young people should take a positive stand in discouraging them from smoking.

For simplicity, the term "chronic respiratory disease" will be used to include chronic bronchitis, chronic obstructive lung disease, and emphysema; and wherever the word "smoking" is used, cigarette smoking is meant unless otherwise specified.

Clinical Experience

Clinical experience suggests a strong relationship between smoking and chronic respiratory disease in men, and several studies have documented a high prevalence of smokers among such patients.[1-3] Mitchell and associates[1] reported that only 5% of a group of patients with chronic respiratory disease were nonsmokers, compared to an estimated 20% of nonsmokers in a "control" population. Of 437 male patients with chronic respiratory disease who were 40 years old or more and were seen in our emphysema clinic, 5% had never smoked cigarettes, compared to 32% in an age-adjusted Mayo Clinic patient population from which most men with chronic respiratory disease had been excluded.

Clinical experience also suggests that patients with chronic respiratory disease who stop smoking fare better than those who continue. When patients do stop, we expect a significant decrease in cough and sputum and, less frequently, improvement in dyspnea. This impression is supported by reports that 63 to 73% of patients with chronic respiratory disease have a significant lessening of cough after stopping smoking.[1,4,5] And among those patients with chronic respiratory disease who stop smoking early enough for a decrease in cough and sputum, the mortality rate has been reported to be significantly less than among those who continued to smoke.[1,5] One study found no difference in mortality among smokers and ex-smokers except that those who stopped smoking after visiting a clinic fared better.[6]

†Mayo Clinic and Mayo Foundation: Section of Medicine.

There is very little information as to what happens to the pulmonary function of patients with chronic respiratory disease and a significant decrease in function when they stop smoking but have no other treatment. In young otherwise healthy smokers, abstinence from smoking for three weeks resulted in a significant improvement in peak flow, pulmonary diffusing capacity, and ratio of oxygen debt to increase in oxygen consumption after exercise. After six weeks without smoking, the functional residual capacity and airway resistance were decreased and the maximal voluntary ventilation was increased.[7] Among 17 patients with chronic bronchitis, however, Fletcher[8] found none whose ventilatory capacity improved significantly after they stopped smoking, though the rate of decline of ventilatory capacity was less steep in those who stopped smoking than in those who continued to smoke.

At the Mayo Clinic we have observed seven patients with chronic respiratory disease and significant decrease in function before and after stopping smoking without concomitant therapy. All reported a reduction in symptoms and four demonstrated an improvement in maximal breathing capacity and maximal midexpiratory flow. Therefore it appears that early in the course of this disease the changes in the airway, as measured by ventilatory tests, are reversible. When the process is advanced, the changes are much more fixed; even though symptoms decrease after smoking is discontinued, improvement in the results of ventilatory tests is variable and relatively slight.

Pathologic Changes

Mucous-gland hypertrophy, the hallmark of chronic bronchitis, has been well correlated with smoking though not with infection.[9,10] When sections of bronchial epithelium from smokers and nonsmokers were compared, those from smokers showed a greater number of goblet cells, more cellular atypism, increased thickness of the bronchial epithelium, greater infiltration of the bronchial epithelium with inflammatory cells, and shorter cilia.[11]

Emphysema

In a post-mortem study correlating the degree of emphysema with smoking, panlobular emphysema was found in a random distribution; but practically all lungs showing centrilobular emphysema came from smokers. The degree of emphysema was greater in older than in younger smokers and also greater in those with 40 or more pack years of smoking.[12] Auerbach and associates[13] found that the degree of rupture of alveolar septa was directly related to the amount of smoking and increased with age; but at all ages, men who had never smoked regularly had far less rupture than smokers. Associated with the disruption of septa were fibrosis, thickening of arteriolar walls, and pad-like attachments to alveolar septa. Ex-smokers who had stopped at least three years before death showed fewer changes than those who smoked to the time of their death. This type of change cannot be reversed by abstinence from smoking, but its progression can be halted.

It has been possible to produce alveolar disruption experimentally by exposing dogs to smoke in a smoking chamber[14] or through a tracheostomy so as to bypass the nose.[15] The lesions produced were considered to be analagous to those found in human emphysema.

Mechanisms Leading to Chronic Respiratory Disease

Increased Airway Resistance

By both direct[16-21] and indirect measurement[22] in smokers and nonsmokers, smoking one or two cigarettes has been shown to acutely increase airway resistance and decrease conductance.

Bronchitics and emphysematous subjects were found to have a greater increase in airway resistance than subjects without airway disease.[17,21] A decrease in compliance in normal as well as in emphysematous subjects after smoking one cigarette has been observed.[23] The apparent bronchoconstriction which has been attributed to irritation of the airway by smoke can be prevented by the administration of isoproterenol[19] or atropine.[20] These changes in airway resistance did not appear in measurements of vital capacity and maximal breathing capacity.[24]

In comparisons of chronic smokers with nonsmokers, the smokers have shown significant decreases in vital capacity,[25-30] expiratory flow rate as measured by any of several methods,[25-27,30-36] and airway conductance[37] and diffusing capacity.[7,28,38] It has also been found that smokers accumulate a greater oxygen debt during exercise than do nonsmokers.[27,39] Anderson and Ferris,[40] in an epidemiologic study which disclosed a significantly greater prevalence of chronic respiratory disease in smokers who had exceeded a threshold of 3,000 packages, found that the forced expiratory volume and the peak expiratory flowrate were decreased proportionately to the quantity smoked. They also detected effects of pipe and cigar smoking in the causation of chronic respiratory disease.

Reduced Bronchial Clearance

Some significant studies in experimental animals have disclosed other mechanisms whereby inhalation of smoke can foster the development of chronic respiratory disease. Bacteria are cleared rapidly from the respiratory tract of healthy mice, indicating that there is an effective clearance mechanism which maintains a sterile bronchial tree; but the inhalation of smoke reduced the clearance of bacteria by 50%.[41] Clearance of small particles that enter the alveoli is accomplished at least in part by phagocytosis.

It has been shown that the clearance of particulate matter is delayed significantly in the period immediately after exposure to tobacco smoke, though the mechanism recovers within 24 hours.[42] This anti-phagocytic action appears to reside in the gaseous or water-soluble component of the smoke, rather than in its particulate component.[43] Ciliary activity is responsible for clearing foreign material deposited anywhere in the tracheobronchial tree to the terminal bronchioles. Exposure to smoke of a variety of membranes containing cilia resulted in a sharp decrease in ciliary activity.[44-46] The ciliastatic effect of smoke also is in its gaseous phase, with hydrogen cyanide, acrolein, aldehydes, and certain acids being most ciliatoxic.

In recent years there has been speculation as to the possibility that disturbances in surfactant influence the disruption of alveoli. Several studies have shown that exposure to smoke decreases the surface-tension activity of material obtained from mammalian lung.[47-49] It has been proposed that this decrease in surface-tension activity or surfactant allows over-distention of large alveoli, thereby leading to rupture of these alveoli and to emphysema.

Summary

Clearly, there is much evidence to demonstrate a relationship between cigarette smoking and chronic respiratory disease; and some mechanisms whereby smoking may produce these changes have been described. Nonetheless, significant gaps in our knowledge remain. For example, not all people who smoke develop chronic respiratory disease in their lifetime, and a few people who have never smoked develop chronic respiratory disease. Smoke is recognized as an irritant to the bronchial tree, but how progression from simple bronchitis to obstructive airway disease and emphysema occurs is not understood. Possibly cigarette smoking is only one factor, albeit a major one, in the development of chronic respiratory disease; and other poorly understood factors such as individual susceptibility, heredity, infection, and exposure to other noxious agents help determine the rate, type, and degree of damage to the lung.

The secret of being tiresome is in telling everything.—Voltaire

Flax Seed Poultice

(A Cataplasm)

Every now and again it is of interest for each of us to look into the past to see what was good in it and what was bad. This certainly applies to the practice of medicine in general and to the use of the poultice, or, as it was known, the cataplasm.

The poultice, which usually was made of a substance termed a counterirritant, has been used since antiquity. Its beneficial effect was felt to be produced by a dilatation of the blood vessels in response to warmth and moisture, thus increasing the blood flow and hastening the progression of the local inflammation to suppuration. Another and more nebulous explanation was that the substance diminished the cohesiveness of the tissue by insinuating itself between the cells, thus rendering the tissue more pliable and soft. Both of these actions tended to increase the swelling which was felt to be beneficial, since it seemed to lessen the tension and pain in the part affected.

Instructions for preparing the poultice were as follows: heat water in a basin until it boils; then sprinkle crushed flaxseed into the water, stirring vigorously till the proper consistency is attained. The substance should then be spread in uniform thickness onto a cloth and applied to the affected part.[1]

Common flax is an annual plant growing about two feet in height and probably originating in Asia or Egypt. Its fruit is a globular capsule about the size of a pea, containing ten seeds, which are oblong and somewhat pointed at one end, brown in color externally and yellow on the inside. The cuticle of the seed contains a peculiar gummy matter readily imparted to hot water, thus forming a viscid, mucilaginous fluid. Ground seeds become flaxseed meal; this has a mild gray color, is highly oleaginous and, when mixed with hot water, forms a soft adhesive mass, which makes an excellent emollient poultice.[2]

In the early 20th century the poultice fell into disrepute (at least in the teaching centers) and, in an official text,[3] was termed a filthy practice conducive to the multiplication of bacteria. Nonetheless, the practice of applying moist heat to an affected part continues to be an extremely important and often used treatment today for localized inflammatory conditions. The most exciting material used recently for local application is DMSO (dimethysulfoxide), an unusual solvent that is derived from a common waste product in paper manufacture. The list of beneficial effects produced by this peculiar substance is long,[4] and resembles in many respects those attributed to the old discarded flaxseed poultice.

Perhaps the poultice or cataplasm will have to be resurrected. Stranger things have happened.

The Physiology of Immunity*

RICHARD HONG, M.D.†
Minneapolis, Minnesota

It is appropriate to review the physiology of immunity and then see how the departure from this developmental process leads to certain respiratory problems directly resulting from immunologic deficiency.

The Recognizer Cell

We envision the antigen as being picked up by a cell which is not clearly defined morphologically and we can call this a "recognizer" cell of some sort (macrophage?). After this initial interaction the "recognizer" puts forth some kind of material that is called superantigen by many people and seems to bear some relation to RNA because if you treat such a material with RNAse it loses its potency. This material is picked up by another cell which we can denote as a processor cell. All of these steps seem to be necessary to produce the material that can be actually picked up by an effector cell and in the final analysis yield competent immunity. We have over the past few years divided immunity into those processes which seem to be more cellular in nature and dependent upon cells for their transmission and, on the other hand, those that are humoral, that is, carried in the fluid phase of the serum. The cells that are involved are the plasma cell for humoral immunity and the small lymphocyte for cellular immunity. There is certainly some relationship between the thymus and some effect of these central organs upon the recognition process (afferent limb) ; but again our knowledge on that is rather imperfect (Figure 1).

The Efferent Process

The immunological deficiency syndromes best studied involve disturbance of the efferent processes. As far as the afferent or "input" immune process is concerned we do not really know too much. There are two diseases that seem to be related to this process: *Aldrich syndrome* where there is a deficiency in recognizing antigens which have some sort of carbohydrate nature, and *fatal granulomatosis* associated with inadequate killing of intracellularly phagocytized organisms. The bulk of the immunologic deficiency syndromes that we have studied more extensively through the years have all been on the efferent side. We can diagrammatically envision how this comes about (Figure 2).

---

†Department of Pediatrics, University of Minnesota.

First of all, there is some sort of primitive cell which is acted upon by the bursa or the thymus which bears a relationship to the lymphoid system similar to that of the pituitary and endocrine systems, being sort of master glands. A multipotential lymphoid stem cell which you might call an immunocyte traffics to the thymus, and from this interaction comes competent cellular immunity. In an alternative route the "immunocyte" is acted upon by an analogue of the bursa of Fabricius, an organ which is well characterized in the chicken and which probably has a counterpart in the intestinal tissue of mammals.

What can be seen in Figure 2 is that if there are processes acting at certain levels in the course of differentiation, the various known disease syndromes can be predicted. It is apparent that a defect of the "stem cell" or immunocyte results in an absence of both cellular and humoral immunity (Swiss type agammaglobulinemia or lymphopenic agammaglobulinemia). The milder forms, of course, would be where the process appears at a later point in this differentiation scheme, giving rise to primarily humoral deficiency or primarily cellular deficiencies.

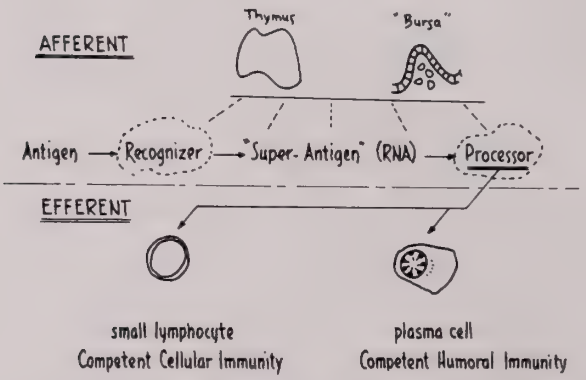

Fig. 1—The afferent (input) and efferent (output) limbs of immunity. The undefined regulatory influence of the thymus and "bursa" are indicated by dotted lines. The morphology of the cells involved in the afferent processing are as yet not wholly defined.

Cellular Immunity

Figure 3 shows a way of looking at the process of cellular immunity and how it reaches full expression. The cell that is of importance in carrying out cellular immunity is the small lymphocyte. It produces a compound called migration inhibition factor which is probably a chemotactic agent which attracts macrophages to the area where an interaction is taking place between antigen and lymphocyte. The macrophages amplify the system and produce the manifestations of the inflammatory response that we associate with this type of immunity. The role of complement in cellular immunity is not as well defined and seems to be more important on the humoral side, as we shall see. Now if one has intact cellular immunity, then he should be able to manifest all of the processes that we test by cutaneous delayed hypersensitivity. We feel that cellular immunity is important in protection against the processes of tuberculosis and monilial infections and in the prevention of generalized vaccinia; and it probably plays a role in giant-cell or Hecht's pneumonia.

Delayed hypersensitivity and cellular immunity are also of importance in the homograft rejection. Though all of these processes can help there are times when, in the process of the protection, the intensity of the inflammatory reaction is such as to cause damage to the host, so that, as an innocent bystander, the individual is harmed worse than the invading antigen. We feel that cellular immunity, when it gets out of hand, can give rise to a class of problems we know as the auto-immune disorders.

Immunoglobulins

As far as humoral immunity is concerned, the important mediators are immunoglobulins; we have at least five and I am sure more will be described in the future. The more important ones are IgG, IgA and IgM; IgG comprising about 85% of the normal immunoglobulins; IgA about 10% and IgM about 5%. The amounts of IgE and IgD are infinitesimal. As in the cellular system, something is needed to amplify the system because the initial reaction of the antibody with the antigen does not seem to do much. If complement is added to the system one can so magnify this reaction that it has profound biological implications. Thus with an intact humoral system you can carry out the processes of agglutination, phagocytosis, opsonization, chemotaxis and lysis, which provide full protection.

One of the interesting concepts of the role of immunoglobulins is that immunoglobulins may act in a protective way by covering cells and preventing anaphylactic reactions by occupying sites on effector cells so that complement cannot get on board. Furthermore, we feel that in certain instances immunoglobulins can coat cells and prevent the destructive action of complement. As in the cellular processes when the mechanism gets out of hand we have the destructive processes of the normal humoral immunity, e.g., the Arthus reaction, the antigen-antibody complex disease, post-streptococcal nephritis, lupus erythematosus and also auto-immune thyroiditis.

Amplification System

Figure 4 shows the amplification system of complement. There are nine components of the complement system and they seem to go on board a membrane surface after the antigen and the antibody combine. The complement continues in a sequence of one, four, two, three and so on to number nine. As these components are added, more biological processes become possible, such as chemotaxis, anaphylaxis, etc. Thus where there was originally an antigen-antibody reaction which was biologically impotent, now one can carry out the processes of immune adherence, chemotaxis, etc.

The persistence of more than one type of immunoglobulin over these many thousands of years of evolution indicates that there is a very definite survival advantage in having different kinds. If we look at the various processes that can be accomplished by humoral antibody and compare the various immunoglobulins one against the other we can see that there are certain specific advantages. ample, if you take agglutination and assign to IgG an arbitrary value of one, the IgM molecule is 750 times as effective as an agglutinator and more efficient in phagocytosis (about 2000 to one as Cf. IgG). We do not know the role of IgA and IgE in any of these processes. Complement fixation is two times as effective with IgM as compared to IgG. IgG, on the other hand, is the only protein that crosses the placenta and therefore provides passive neonatal immunity. Reagin activity has now been localized to IgE. That does not seem like a very beneficial process at the moment; I imagine that reaginic activity is probably an uncontrolled or destructive action, so that we shall therefore have to look further for the beneficial effects.

Blocking Antibodies

The concept of blocking antibody, of course, is very interesting to all physicians who treat chronic allergic syndrome, and work by Dr. Lichtenstein at Johns Hopkins has shown that upon sensitization by local injection you produce in the serum a lot of IgG antibody which has the ability to block the destructive IgE reagin. In the secretions, e.g., the saliva, the IgA is an important antibody which block, the IgE.

Localization to secretions stimulated by exterior influences is a characteristic quality of the IgA system. We feel that it may be of importance in providing local protection if, for example, you get invasion of the gastrointestinal or the respiratory tract. Rheumatoid factor activity is primarily the function of IgM. We think that the rheumatoid factor may be a form of protective type of activity and that the IgM may act to coat surface membranes preventing further antigen-antibody complex injury or blocking complement fixation.

Conclusion

In summary, we can conclude that IgM is probably important as a first line of defense; IgG is important for long-lasting immunity and the blocking of antibody, and IgA is important in local secretion.

The School of Salerno

What Meat To Eat

It followes now what part of every beast
Is good to eate: first know the Heart is ill,
It is both hard and heavy to digest.
The Tripe with no good iuyce our flesh doth fill:
The Lites are light, yet but in small request:
But outer parts are best in Physicks skill.
If any braines be good (which is a question)
Hens braine is best and lightest of digestion.

Regimen Sanitatis Salerni

The school has nothing good to say about heart and tripe; the lungs are without substance and rarely requested. The school advises that the skeletal muscle meat is most desirable. If brains are to be consumed, the authors roguishly add that hen's brains are in order.

The Nature of Disease

What disease is, is by no means a foregone conclusion, even if we eliminate all supernaturalistic explanations. Actually opinions about the nature of disease have greatly changed during the last 100 years and are still changing.*

One pancake for lunch and half a boiled egg for dinner makes a man at sixty able to do anything a college athlete can do.—William Osler

Hyaline Membrane Disease*

Danger of a Rational Approach to Therapy

V. CHERNICK, M.D.†
Winnipeg, Manitoba

HYALINE MEMBRANE DISEASE has traditionally been thought of as having a 72-hour course with either death of the infant or recovery by that time. Although the disease is one of the major causes of death of the premature infant‡ it has been only in the last decade or so that sophisticated techniques of pulmonary physiology have been adapted to the premature infant. This information, compiled by a great number of investigators, has led to an increase in our understanding of the pathophysiology of this disease and to a therapeutic approach designed to overcome the physiologic derangements. Thus, by utilizing a rational approach to therapy we have been able to alter the course of this disease, but not without induced complications.

Incidence

The incidence of this disease is related to birth weight with the highest incidence, whether related to the number of births or to the number of deaths, occurring in the 1-1.5 kg group. In this weight range about 20% of liveborn infants are affected, and 45% of the deaths are from hyaline membrane disease. Considering all low birth-weight babies from 1-2.5 kg birth-weight, hyaline membrane disease affects approximately 8 to 10 percent of liveborn babies but accounts for about 40% of the deaths of these infants.

Pathology

Characteristically, the disease consists of severe atelectasis with dilated proximal bronchioles and alveolar ducts. It is in these dilated air-containing spaces that one sees the classical hyaline membrane and, therefore, the disease does not appear to be obstructive in nature.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Associate Professor of Pediatrics and Physiology, University of Manitoba and Director, Respiratory Service, Children's Hospital, Winnipeg.

‡Now called the low birth weight infant.

Surfactant

One of the most significant advances in our understanding of this disease came in 1959 when Avery and Mead[1] reported that in infants dying with hyaline membrane disease the surface tension of the saline extracts of lung was abnormally high. The normal lung contains a surfactant which acts as an anti-atelectasis factor.

The transmural pressure or collapsing pressure of air spaces or alveoli connected in parallel is dictated by the LaPlace relationship which states that the collapsing pressure is proportional to the surface tension and inversely related to the radius of curvature. Thus, in alveoli of dissimilar size the collapsing pressure is highest in the smaller alveolus, which then tends to empty its air into the larger alveolus when the surface tension of the two alveoli is the same. However, the lung normally has an alveolar lining layer of surfactant which has the ability to lower its surface tension to very low values when the radius decreases. Thus the collapsing pressure of two alveoli of dissimilar sizes can be identical and there is no longer any tendency for small alveoli to empty into large alveoli. The term anti-atelectasis factor, therefore, seems appropriate when describing lung surfactant.

The pulmonary surfactant is presumably a lipoprotein complex, and the lipid portion of this complex is a lecithin, that is, a phosphatidylcholine which contains saturated fatty acids at the alpha and beta positions. Analysis of lungs of infants dying with hyaline membrane disease has revealed a decrease in the amount of disaturated lecithin. The lungs of infants who have died following recovery from hyaline membrane disease, and infants dying of non-pulmonary disease have higher concentrations of desaturated lecithin and very low surface tensions.

Pressure-Volume Studies

In-vitro studies of the lungs of infants dying with hyaline membrane disease have increased our understanding of the physiologic derangement in this disease. When these lungs are fully inflated to 35 cm of water pressure and the pressure decreased in 5 cm of water pressure decrements, the lungs of such infants contain less volume at each transpulmonary pressure when compared to lungs of newborn and stillborn infants without hyaline membrane disease. Furthermore, at zero transpulmonary pressure the lungs of babies with hyaline membrane disease cannot contain any air, but go on to complete collapse, while those of stillborn and newborn infants can still contain air following inflation even at zero transpulmonary pressure. This tendency to collapse, or atelectasis, is the fundamental problem in the disease.

Etiology

Over the years there have been numerous theories of the etiology of hyaline membrane disease, and to some extent our treatment of this disorder has been based on the theory of pathogenesis to which we happen to subscribe.

Aspiration of Gastric Content

One of the earliest theories was that of aspiration of gastric contents, but there is little evidence for this at the present time. However, the custom of emptying the stomach of premature babies at delivery still persists in many delivery rooms.

Asphyxia

There is no question that infants with hyaline membrane disease have lower Apgar scores at birth, suggesting that asphyxia may play a role. The increased incidence of the disease in the second of twins also supports asphyxia as a primary insult.

Cardiac Failure

There is little evidence on the basis of catheterization data that these babies have cardiac failure; however, there are some who feel digitalis is indicated.

Decreased Blood Volume

The decrease in mortality from hyaline membrane disease when the baby has had a large placental transfusion suggests that decreased blood volume may play a role.

---

*See Test Your Word Score page 1401.

Deficient Fibrinolytic Enzyme

There are some studies which indicate deficient fibrinolytic enzymes in the lungs of babies dying with hyaline membrane disease. Whether these are primary or secondary to the disease is unknown, but there are nurseries where fibrinolysins are aerosolized to the lungs as part of the therapy, and the preliminary results are encouraging.

Altered Vagal Tone

Since vagotomy in animals results in pulmonary edema and hyaline membranes, and since severely ill babies with hyaline membrane disease have abnormally high constant heart rates, it has been suggested that the disease is associated with disturbed autonomic regulation.

Current Theories

The two leading theories at the present are that there is a primary deficiency of surfactant on the basis of prematurity alone, or that there is a primary defect in the pulmonary circulation, so-called pulmonary hypoperfusion or ischemia which secondarily alters surfactant. However, attempts at increasing the pulmonary circulation using acetylcholine have not improved the mortality rate from this disease.

Therapy

Energy Metabolism

The infants are kept warm, in a neutral thermal environment (anterior abdominal skin temperature of 36.5°C) which is associated with a minimal oxygen requirement. Oxygen is supplied in sufficient concentration to keep the arterial PO_2 within relatively normal values. The babies are given fluids and glucose for energy metabolism, and intravenous bicarbonate is used to correct metabolic acidosis.

Artificial Ventilation

In the presence of severe respiratory failure artificial ventilation is used to combat carbon dioxide retention and respiratory acidosis. The usual mode of artificial ventilation has been the use of endotracheal intubation and positive pressure respirators. However, recent reports by Northway[2] and co-workers from Stanford University have indicated that babies who receive prolonged artificial ventilation and high concentrations of oxygen are susceptible to the development of a condition termed bronchopulmonary dysplasia. We have seen this complication in our own nursery after about six days of endotracheal intubation and artificial ventilation.

Complications

Diffuse Interstitial Fibroplasia

This complication is characterized by the appearance of severe diffuse bilateral pulmonary infiltrations which appear after about six days of respirator therapy. The infiltrations may impart a "bubbly" appearance to the lung, not unlike that seen in the so-called Wilson-Mikity syndrome. The disease eventually progresses to a stage of marked hyperinflation of the lungs which can be recognized both clinically and roentgenographically.

The lungs of these babies show at post mortem a thickening of the alveolar septal walls with lymphocytic infiltration and multiple areas of fibroplasia and even collagen formation. We have not seen the bronchiolar epithelial hyperplasia described by Northway et al. and therefore have used the term diffuse interstitial fibroplasia to describe the roentgenographic and pathologic changes.

Over a 2½-year period at the Winnipeg Children's Hospital with a very highly selective and severely-ill population of infants we had 51 newborn infants who received artificial ventilation; 45 of the 51 were premature and 38 weighed less than 2 kg at birth.[3] Thirty-seven of the babies had an initial diagnosis of hyaline membrane disease and 14 of them required treatment because of aspiration pneumonia, tracheoesophageal fistula or a neonatal pneumonia.

Of those babies with hyaline membrane disease 27 were ventilated for less than six days and 18 of these died despite intensive therapy, reflecting the high mortality from this disease in the first few days of life. Of those who were ventilated for more than six days, two died and eight survived. Both of the babies who died had diffuse interstitial fibroplasia at autopsy. Four of the eight who lived had radiologic evidence of diffuse infiltrations on their chest films at one stage of their illness. Of the 14 who were ventilated for conditions other than hyaline membrane disease, diffuse interstitial fibroplasia again appeared only in five babies ventilated for more than six days. Thus, out of the total of 16 infants ventilated for more than six days, there were 11 examples of diffuse interstitial fibroplasia. We have had follow-up examinations of seven of the nine who survived, and surprisingly these diffuse infiltrations on the chest film have either disappeared or vastly improved, and these babies do not appear to have chronic respiratory difficulties.

Oxygen Therapy

Of those babies who were ventilated for more than six days, five had received high concentrations of oxygen (> 80%) for a period of less than 24 hours and despite this still developed diffuse interstitial fibroplasia. There were three who did not develop diffuse interstitial fibroplasia who also received high concentrations of oxygen for less than 24 hours. Of the nine receiving high concentrations of oxygen for more than 24 hours, six developed diffuse interstitial fibroplasia; yet there were three who did not develop this complication. Thus, it seems from our experience that there is no direct relationship between the duration of high concentration of oxygen therapy (> 80%) and the presence or absence of diffuse interstitial fibroplasia.

Endotracheal Tube

Some of the possibilities which have not been investigated thoroughly are that the endotracheal tube may in some way be related to the appearance of this disorder either by causing damage to the larger airways or by reducing effective ciliary activity, thereby resulting in abnormal accumulations of pulmonary secretions.

Constant Tidal Volume

There have been numerous studies in adult humans and animals which show that a constant tidal volume predisposes to areas of atelectasis and reduced lung compliance. That is, when one breathes at a constant tidal volume, the lungs tend to become atelectatic, and presumably this is why normal respiration is interspersed with frequent sighing and the occasional deep breath. That this may be a factor in this complication is a distinct possibility in view of recent preliminary reports by Doctor Stern of the Montreal Children's Hospital. In his nursery he does not use endotracheal intubation and positive pressure respirators for artificial ventilation. Instead, he uses a tank-type negative pressure respirator in which the baby, if he wants to, can cry to take a large breath. He has not seen this complication despite the use of very high concentrations of oxygen.

Other Complications

Other complications have arisen as a result of our current approach to therapy of hyaline membrane disease, such as pneumothorax, lobaratelectasis and pseudomonas infection secondary to the use of endotracheal tubes and respirators. Since the advent of the use of high concentrations of oxygen several cases of retrolental fibroplasia have appeared. To prevent retrolental fibroplasia we are now attempting to monitor the arterial oxygen tension in every infant by inserting a catheter into an umbilical artery. However, this procedure is not entirely benign since we have had one case of extensive thrombosis of the distal aorta and external iliac arteries.

Concluding Summary

Clinical experience has increased our understanding of the pathogenesis of hyaline membrane disease and suggests a therapeutic approach based on the correction of the physiologic abnormalities. Because of our experience with iatrogenic pulmonary disease it has become necessary to alter the approach to therapy. At the present time it is hoped that diffuse interstitial fibroplasia can be prevented by the use of endotracheal intubation and positive pressure ventilation for a maximum of six days. If artificial ventilation is needed after that, the babies will be transferred to a tank-type respirator. In addition, frequent measurement of arterial oxygen tension and much closer attention to frequent suctioning and pulmonary toilet seem to be important. It is too early to tell whether this regimen will make any difference.

Let's be specific about Campbell's Soups… and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Calorie content of Campbell's Soups

Campbell's
SOUP

NOW IS THE TIME... TO GIVE HER TIME WITH OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The new mother needs time...
to adjust to motherhood,
to give her new baby all the love
and attention he requires.
She needs time for her husband...
and for herself as well...
so that she can come to terms
with the increased cares
and responsibilities now facing her.
She needs time to decide
when she will have additional children
and how many she will have.

OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

GIVES HER TIME

Your prescription for Ovulen-21 gives the new mother time to meet her family's present needs...to plan for her family's future.

She can take Ovulen-21 confidently and comfortably month after month. Its dependability is enhanced by its simplicity of use. A woman needs little or no time to learn the simple Ovulen-21 regimen: three weeks on—one week off. And the automatic record-keeping of the petite, virtually "patient-proof" Ovulen-21 Compack® helps to maintain her schedule...helps put time on her side.

Immediately post partum is the time

It is the time when motivation is highest—when a new mother needs expert advice for the future, so she can space her children and limit her family.

It is also the most opportune time, since she is conveniently present in the hospital, for her to be given both instructions and a prescription.

Non-nursing mothers may begin Ovulen-21 immediately after delivery, on the day of departure from the hospital or at the first postpartum visit, as desired. It is recommended that nursing mothers begin Ovulen-21 four weeks after delivery.

A small fraction of the hormonal agents in oral contraceptive pills has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching. The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

PRESCRIBING INFORMATION. 11—1/2/69. For complete information consult Official Package Circular.

Indications: Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *S. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci).

Contraindications: A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms.

Precautions: Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy.

Adverse Reactions: Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets.

Usual Dosage: Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis—150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days.

Supplied: Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

The National Cystic Fibrosis Research Foundation and Chronic Respiratory Disease in Children and Adolescents*

At a time of increasing complexity in science and society alike, there is a paradox at work. On the one hand we are forced into separateness and specialization; on the other, there are growing areas of shared interest, endeavor and knowledge. Certainly this is true in the field of diseases with which the present issue of Minnesota Medicine is concerned.

In 1955 the National Cystic Fibrosis Research Foundation was organized to combat this disorder. That year it awarded its first grant for research. Three years later, in response to increasing evidence of concern among parents, physicians and the general public, the National Institutes of Health also made grant funds available for research in cystic fibrosis. Both organizations have subsequently continued and greatly expanded this support.

Meanwhile, in 1961, a start was made by the National Cystic Fibrosis Research Foundation to establish a network of Cystic Fibrosis Care, Research and Teaching Centers. With the medical schools' cooperation, these were set up in teaching hospitals. Forty centers and 58 cystic fibrosis clinics eventually were in operation. Because many patients referred to them turned out not to have cystic fibrosis but to be suffering from other pulmonary or gastrointestinal disorders, a pattern of service was set that still persists: the majority cared for in these facilities are non-cystic fibrosis patients and are being treated for asthma, bronchiectasis, chronic bronchitis, and other chronic pulmonary diseases. It has followed quite naturally that the Center-clinic staffs have become recognized in their communities as outstandingly qualified to deal both with cystic fibrosis and with these various related conditions.

Something analogous has taken place in research. In the fall of 1965 the National Cystic Fibrosis Research Foundation inaugurated a series of basic research conferences, each one devoted to a subject such as molecular genetics, the autonomic nervous system or the nature of the secretory defect and its location in the sweat gland of the person with cystic fibrosis. Early in 1968 a Symposium on Cystic Fibrosis and Related Human and Animal Diseases was co-sponsored by the Foundation, the National Institute of Arthritis and Metabolic Diseases and the National Center for Chronic Disease Control of the Bureau of Disease Prevention and Environmental Control, U.S. Public Health Service. Over the course of these and other scientific meetings, there has been a shift from the exclusive concentration on cystic fi-

For the "Cheater Eater"

Formulas: Each 'Dexamyl' *Spansule* capsule No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid (Warning, may be habit forming). Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital (Warning, may be habit forming).
Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Hyperexcitability, undue restlessness, hyperthyroidism, porphyria; in patients on MAO inhibitors.
Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence. Rarely, symptoms of toxic psychosis (hallucinations, confusion, panic states, etc.) may occur with amphetamines, usually after prolonged high dosage. In these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester.
Adverse Reactions: Overstimulation, restlessness, insomnia, g.i. disturbances, diarrhea, palpitation, tachycardia, elevated blood pressure, tremor, sweating, impotence and headache.
Supplied: In bottles of 50.

Dexamyl®

SK&F
Smith Kline & French Laboratories

brosis to consideration of molecular diseases in general, and from investigators not previously associated with cystic fibrosis have come valuable insights and suggestions.

When Washington decided last year to create pediatric pulmonary centers, grants went to groups that had already had experience conducting Cystic Fibrosis Centers.

The Regional Continuation Training Course in Cystic Fibrosis and Chronic Lung Disease held September 17-19 at the University of Minnesota Medical School was one of a series sponsored jointly by the National Cystic Fibrosis Research Foundation and the Bureau of Health Manpower Educational Services. The courses are designed to disseminate the latest knowledge about cystic fibrosis and chronic lung disease among members of the medical profession and to acquaint them with resources for further information and training.

As we get deeper into our age of specialization—sometimes thought of as an age of alienation—it is possible to point to greater interrelatedness among physicians, scientists, the government and voluntary health agencies. I firmly believe that, beyond present benefit, this is a portent of things to come.

The Chronic Respiratory Program in the Minnesota Crippled Children Services*

In 1961 many physicians requested financial relief for parents whose children needed many expensive drugs for their chronic respiratory disease. Consequently Crippled Children Services began to provide drugs for these children as well as the diagnostic and treatment services when their parents were unable to provide the care.

The drugs and pulmonary exercises gave bright hope for many children. Parents and physicians were eager to avail themselves of these new advances in treatment.

Administration

All Minnesota children under 21 years of age are eligible for diagnostic services without charge to their parents. These services are available at the general itinerant field clinics, pediatricians and the two medical centers.

Applications for treatment can be obtained from the County Welfare Departments. A social worker will assist the parents in completing the application form. A medical report is needed to complete the application.

Eligibility of the child for treatment is determined by the Commissioner of the Department of Welfare. Consideration is given for other health needs in the family. The parents are notified by the Crippled Children Services as to whether or not the child is accepted for care. It is necessary that the application be approved and the necessary authorizations be issued prior to service.

Emergency service can be arranged for a patient by telephone or wiring the Crippled Children Services.

Physician services, including laboratory and x-ray services, hospital care, and a wide range of drugs are provided. Prescriptions are sent to the Crippled Children Services office, where they are filled by a pharmacist; then the drugs are mailed or sent by bus to the parents. Aerosol equipment is usually purchased by the parents or the County Welfare Department.

Findings

From the beginning of the program for chronic respiratory disease in May, 1961, to July 1, 1968, 85 children in 69 families have received care. Sixteen (23 per cent) of these families have had two, three or four children with chronic respiratory disease. Females (52 per cent) have predominated.

When the size of the family was plotted against the family's gross income group, eight families (12 per cent) were eligible for the medical assistance program.

1964-65	37	8,709.88	420.25	2,612.29	11,742.42
1965-66	50	15,351.06	677.05	11,815.07	28,786.18
1966-67	58	19,393.94	630.30	8,412.62	28,349.11
1967-68		18,526.40	597.30	14,015.79	33,139.49

As these children have been followed, two of them have moved out of the state, and three were discharged at 21 years of age. Fifteen children from the 12 families have been removed from the treatment program because of the parents' ability to pay for their care.

Nine children (three males, six females in eight families) have died. The age range at death was from four months to 18 years; the average age was 8.4 years.

The number of children (Table) served in each fiscal year has increased from 17 to 58 from 1961-62 to 1966-67. The cost of the program has gradually increased from $2,182 in 1960-61 to $30,454 in 1967-68. Insurance payments are utilized but are usually not available for office visits or drugs. The cost of drugs (64 per cent) has been the most expensive part of these children's care. The average cost of care per child in 1966-67 was $488.

Conclusion

From the beginning of Minnesota's chronic respiratory program from May, 1961, to July 1, 1968, 85 children from 69 families have received diagnostic and treatment services when their parents were unable to provide the necessary care. Nine children (11 per cent) have died in this interval at the average age of 8.4 years. Twenty-three per cent of the families have two or more children with chronic respiratory disease and 88 per cent of the families are in the middle class.

There has been a gradual increase in the number of children provided for under the program and a corresponding increase in the cost of the program. The cost of drugs was 64 per cent of the total cost. The average cost of care for each child in 1966-67 was $488.

Public Health Nursing Care of Chronically Ill Children*

IN THE VERY NATURE of chronic illness in any age group lies the implication for a long period of care and management, with the home as a primary focus. Those in the home who bear responsibility for long-term care of any ill person need assistance with care, instruction in giving care themselves, understanding of the illness and of medical orders, and support in persevering in the face of physical, emotional and financial burdens. A whole new element is introduced which must somehow be absorbed if family life is to be continued with any normalcy. When the patient is a child, these needs are multiplied in intensity for the family and especially for the mother who is usually the person responsible for care. When the child's illness involves the respiratory system, difficulties in breathing are particularly frightening and distressing.

Regardless of social and economic status, most of us in our society find it difficult to accept a chronic illness, particularly one with a

poor prognosis, at a time in the life of the individual that we believe should be a beginning, or at least a period without adult pain and worries. Such feelings are, of course, intensified for parents, especially if the illness has some genetic factor. Yet, in the face of such responsibilities and worries, a mother must somehow try to go about the business of beginning care if the illness is newly identified or resuming care if hospitalization has intervened in a long illness. The diagnosis of a child's chronic illness is usually a time of crisis, as is hospitalization or a crisis involving other family members. Death, of course, is the supreme crisis to be faced. If we are present in the home during or shortly after a crisis to help as needed, we may be able with relatively little effort to make a difference in the way a family adjusts initially; and the likelihood of our being more helpful in the long pull of chronic illness is greater, especially if subsequent crises are faced. Public health nurses can be helpful at such times; but their services are not and should not be limited to these.

We have the advantage of being able to go into the home, to work along with the mother in giving physical care if needed, in devising ways to give medications and to be sure these are understood, in setting up and using special equipment, and in planning for special diets. Above all we can visit often enough and long enough to give attention to the mother and her concerns and to consider with her the implications for the family. Even the most adequate mother who is busy with the care of a family as well as the care of a chronically ill child experiences a sense of isolation, and at times discouragement, as weeks and months—even years—provide no let-up in her responsibilities. The nurse can be supportive to her in many ways, depending on her needs and those of the child. She can give her some relief from actual physical care either by visiting herself or in some instances by teaching a practical nurse or home health aide how to give the care. She can encourage the mother to persevere in the often difficult tasks of treatment. She can help parents to consider such areas as school activities and to work with teachers if modifications are indicated.

In all of this, she must work closely with the physician in order to keep abreast of the physician's plan of treatment and changes in the child's condition. She can serve as a frequent and objective observer and reporter of progress and changes because she has a unique opportunity to be present in the midst of ordinary activity, without other demands being made on her for the moment, and to participate as needed in whatever care is required. She is also accepted, by many patients at least, as someone like themselves, yet as a professional who can listen to the day-by-day progress and problems, as someone who is not too busy and who understands. This may be all that some families need. If services other than nursing are needed, the nurse can often help to identify such needs and encourage families to seek other kinds of help and to follow through. Also she will need to work closely with physicians and workers providing other services.

Community nursing services receive some public support, either from taxes or voluntary funds, which enable them to give service at cost and to adjust charges according to a family's ability to pay. Medical assistance programs are available to families whose income falls below a specified level. In Minneapolis special programs are available, funded by the Childrens Bureau, to assist with medical care for children not eligible for other funds and living in the designated project area.

In most large cities public health nursing services are available on request from a visiting nurse association or a city health department. In Minneapolis these two agencies are combined into one nursing service for the city. Service may be initiated by a telephone call; but we require confirmation of telephone orders in writing. However, service can begin as soon as we receive a request and any necessary medical orders by telephone. In addition to the nursing services discussed, a physical therapist is available as a consultant to assist the nurse in carrying out exercise and rehabilitation programs.

In Minnesota services are available in 77 counties, and requests may be made directly to the County Public Health Nursing Service. Some of these nursing services provide consultation by a physical therapist, and some also have home health aides to extend public health nursing services. In the 10 counties without

Observations of a 28-Year-Old Man with Cystic Fibrosis*

THESE THOUGHTS of a 28-year-old man with cystic fibrosis are presented with the hope that they may help others to understand the problems of the young adult with that disease.

To parents I say, from the time your child is born with cystic fibrosis until the time he goes out into the world as an active and productive adult, you must keep a watchful eye and try to use the guidelines that govern the life of a normal child.

Try to instill in him the feeling that he is just as normal, within limitations, as most other children. He must be made to feel that he is part of humanity rather than a small singled-out specimen to be held in awe by others as well as himself!

Don't isolate him from the outside world. Teach the child, and especially the adolescent, to think for himself. As parents you have a real obligation to prepare each of your children for an active role in life. The obligation is even greater when you consider that your child is entering society with one black mark against him. *He has cystic fibrosis!* Early in life teach him how to solve his own problems; to run his own interference; to cope with the problems of living and to face the world on his own two feet. Don't be overprotective; love him but don't smother him.

As your child gets older and becomes an adolescent try to instill in him the feeling that he belongs to society and that he must some day in the not too distant future enter it on an active, productive level.

If he has always had to jump his own hurdles and to think for himself in his earlier years, he should be able to face the prospect of being a part of society as an active and productive individual, on par with a normal person.

In the 40s and 50s, when I was growing up, many children with cystic fibrosis died at an early age. Consequently, parents raised their "cystic children" in an over-protective manner and never gave much thought to the fact that the child would ever have to face the world. Presently, more and more cystic children are living well into their teens and adulthood; in fact, with the use of proper therapy, most cystics can have—within reason—a normal healthy life. With this idea in mind, the parent *must* gear the child and adolescent to that goal.

Give your child the proper therapy prescribed by your doctor! If the child is old enough to manage therapy himself, make sure he does so. I can't express too strongly the necessity of using a good therapeutic routine. Remember that if you are steadfast in using a good therapeutic program when the child is young, this same practice will manifest in the adolescent and young adult.

Put yourself in the position of the cystic: think to yourself "How would the world look to me if I felt ill all the time?" Then think "How much better the world looks if I feel well much of the time." I say that with the constant use of proper therapy the "cystic" *can* feel well much of the time.

When we have a sound mind and a healthy body, and in this case I mean a body that is therapeutically well cared for, we certainly can put our best foot forward and look ahead to a good life with a future . . . something we haven't had the opportunity to do in the past.

ADVERTISING COUNCIL · PUBLIC SERVICE ·
RELIGION IN AMERICAN LIFE

To businessmen I say, an individual with cystic fibrosis has a chronic physical disability which can be managed with proper therapy, just as a diabetic is managed with insulin or a heart patient with digitalis.

We are coming into an age where medical progress has made it possible for these cystic children to grow to adulthood. In most cases these individuals are above average in intelligence and *can* be productive human beings. They *want* to be productive human beings: independent and self-supporting. But sometimes it is almost impossible, when everywhere they seek employment they are rejected because they cannot pass the physical or cannot be covered by company insurance. Whether or not they can fulfill the other job requirements is of no consequence. This is very discouraging! And after a person has been repeatedly rejected, he loses his determination and resigns himself to defeat. The result is depression and eventually the realization that life has no more future than death, since society will give him no chance to support himself.

Education of the public as to what cystic fibrosis really is, is a major concern to us now! In the next few years there will be many "cystics" looking for employment, and I hope that, with understanding, business and the public will be ready to receive them.

Parents have the responsibility of giving their children the guidance necessary to develop into independent, self-sufficient individuals who understand the importance of their therapy for the maintenance of physical health, thus enabling them to become ambitious, conscientious adults with the desire to work and lead productive lives as useful citizens.

Letter to the Editor

As you probably know, the Massachusetts Medical Society is the oldest medical society with a continuous history in the country. At the present time, the Society is in the process of updating the statutes of 1781 that govern the organization. We began a series on the history of state medical societies, written by the editors of the various state medical journals in our January issue.

Can we prevail upon you to write an article on the Minnesota Medical Society and include germane information on MINNESOTA MEDICINE? If you find the suggestion intriguing enough and if your schedule allows it, may we have such an article? I look forward to hearing from you soon. Incidentally, I enjoyed the editorial on Purism and agree with the author's comments. I think your journal is absolutely super!

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

Letter to the Editor

For some time I have been planning to write to you to thank you for the complimentary copy of your fine journal which I receive monthly and which I presume you send to all AMA delegates. Now I am prompted to write both out of gratitude and out of curiosity.

First the gratitude: I enjoy and look forward to receiving your journal each month. After reading it I take it to the hospital for the library where it is read by another four hundred doctors and some sixty members of the House Staff. So you see we get considerable mileage out of your courtesy.

And now the curiosity: As a freshman medical student thirty odd years ago I spent one entire Sunday afternoon dreaming up a mnemonic for the branches of the external carotid artery. I finally came up with "All shyster lawyers enjoy sharing other people's surplus income." This has stood me in good stead for many years and I can still name the branches of the external carotid for whatever use that may be. I was intrigued by your note on Page 901 of the June issue of the MINNESOTA MEDICINE in which you refer to two well-known old-timers, but the "As she lay extended Sir Oliver . . ." was a brand new one to me. Inasmuch as my curiosity has gotten the better of my reticence I wonder if you would mind completing the quote?

President's Letter

Medical Students

The demonstration by nearly 200 young people, including residents, interns, medical students and other groups at the A.M.A. convention in New York City on July 13 is well known to all of you. I can tell you, categorically, that the dissident medical personnel were in the minority. The others included heterogeneous groups seemingly demanding attention without valid reasons.

Seventy bonafide medical students, attending the House of Delegates, were nonparticipants in that irresponsible demonstration. A number of them came of their own accord to the headquarter rooms of a number of the state delegations to state that they did not agree with the demonstration and that these protestors did not represent student thinking. However, these students and a significant number of others do have a sincere concern relating to the field of medicine ranging from medical school admission policies and school curriculum, to the delivery of medical services. These students have become activists in promoting change. They are organized into two principal groups: the Student American Medical Association and a new group named Student Health Organization. Both of these organizations are becoming politically powerful.

The Student Health Organization, composed of medical, dental and nursing students plus various para-medical personnel, requested to be heard before the House of Delegates of the Minnesota State Medical Association meeting in Minneapolis in May, 1969. The spokesman for Student Health Organization made it clear to our House of Delegates that they first wished to become known to the practicing physician as friends and to get better acquainted with members of organized medicine. Student Health Organization policy makers state that they have great concern with social change and feel that such change be brought about through direct political action and community involvement. Their concern is for all levels of society including the disadvantaged: migrant workers, Indians, Mexican Americans, Blacks, and others.

The Student Health Organization has been active in several projects including participation in the Pilot City Health Care Center in Minneapolis, curriculum revision with emphasis on lectures on medical, social, urban, drug and alcohol problems and other topics, and racial and ethnic minority admissions to the health professions by changes in attitude of admissions committees.

The Student American Medical Association also has strong attitudes regarding changes in medicine.

Acknowledging that many responsible medical students are intensely interested in being heard by organized medicine and that these students do have many constructive and new ideas, our House of Delegates set up a subcommittee named the Subcommittee on Residents, Interns, and Medical Students. This subcommittee is meeting with representatives of the student body to study the problems that today face residents, interns, and medical students.

I believe these groups indicate a healthy movement for medicine. These young men and women will be the doctors of tomorrow, as well as the members and leaders of organized medicine. Let us support their constructive and new worthwhile ideas to the fullest extent.

Delmar R. Gillespie, M.D.
President
Minnesota State Medical Association

Editor's Soliloquy

Meleagris Gallopavo, Homo Sapiens, and Pig

THE KINSHIP of man, lower mammalian and avian species was again brought home to your Editor when a colleague was obtaining a history from one of his patients: an agriculturist suffering from a bleeding ulcer and a large abdominal aneurysm, who informed us that neither disease was new to him.

Pigs, he told us, are very susceptible to bleeding peptic ulcers: the leaner the hog the greater the danger. That made us wonder! By demanding our breakfast bacon lean may we not be building up frustration in Porky, whose very nature inclines him to be fat?

What's more—hogs can even become "nervous wrecks," when they are loaded on the truck for the trip to the slaughterhouse. Probably not so much because they don't know where they are going, but because they are too crowded on the way; which reminds us that psychologists say that too much togetherness can be devastating to the nervous system. Fish, rats, monkeys, don't behave or function normally when too crowded for too long. They become irritable, pugnacious, and averse to eating, sleeping and mating. Perhaps that includes Porky who, some hog raisers aver, is not the stupid, gross farmyard animal we thought, but indeed quite a sensitive fellow.

Abdominal aneurysms, our agriculturist further informed us, are a common disorder of the domestic turkey and, although aortic rupture occurs as a sporadic, spontaneous, fatal hemorrhage with flock mortality as high as 20 percent, the etiology remains obscure. Is it possible that our epicurean demand for broad-breasted Thanksgiving birds may have something to do with aneurysm phenomenon? Have we likewise interfered too much with the turkey's natural build and body proportions in order to serve more succulent white breast at our dinner table? I'm a thigh man, myself!

Our veterinary colleagues[1] from the St. Paul Farm Campus of the University of Minnesota have rendered us valuable service in producing lean, though nervous pigs, and broad-breasted, though aneurysm-prone turkeys. Also much commendable effort is being expended by the veterinarians in studying hypertension, heredity and hormonal factors on the production of porcine neurosis and meleagrine aneurysms. But it is here that our human and veterinary medicine must part—at least for the present.

Our agriculturist calmly submitted himself to the surgeon for replacement of the aneurysm with a new plastic aorta and a vagotomy for the bleeding ulcer. The eugenics can wait.

Laboratory Letter

Triglycerides, Too

Can you sift out with a single test those patients who are destined to have a coronary occlusion? You can't, of course, not with one test or a dozen. But from the work of recent investigators, this much is clear—a serum cholesterol and serum triglycerides too can give you a rough idea of whether a patient is coronary-prone.[2]

Why? Because hypertriglyceridemia, like hypercholesterolemia, seems to predispose to premature atherosclerosis. Yet high serum triglycerides aren't necessarily coupled with high serum cholesterols. Kuo, for example, studied 286 atherosclerotic patients, many of whom were young men with coronary artery disease. Only 8.4% had an isolated high cholesterol, while 9.8% had only high serum triglycerides, and 81.8% had elevations of both.[1] To compare our data with his, I have taken sera on which we measured both triglycerides and cholesterol, separated out those samples where either or both tests were up (here I used Kuo's upper limits of 250 mg/100 ml for cholesterol and 150 mg/100 ml for triglycerides), and compiled the resulting data into Table 1.

As you can see from the table, if you had applied Kuo's upper limits to judge our patients' lipid status and if you had ordered only a cholesterol, you would have missed 44.4% of patients with hyperlipemia. A word of caution, though, lest you leap to conclusions. Though Kuo's upper cut-off points may be desirable, I don't consider them normal. I believe you ought to take age and sex into account before you label patients as abnormal. In Table 2, I show our age and sex-adjusted normal ranges.

TABLE 1

Distribution of Cholesterol and Triglycerides in 252 Sera

T.G.	Chol.	Number of Sera	Percent
normal	high	51	20.2%
high	normal	112	44.4%
high	high	89	35.4%

TABLE 2

Age and Sex-Adjusted Normal Ranges for Cholesterol and Triglycerides

Age	Sex	T.G.	Chol.
20-29	M	10–140	110-215
	F		85-250
30-39	M	10–140	120-250
	F		125-265
40-49	M	10–150	135-305
-	F		135-265
50-59	M	10–160	150-310
	F		140-305
60-69	M	10–190	145-325
	F		150-325

Finally, a few practical points. First, triglycerides tend to be high in overweight patients with mild diabetes and coronary artery disease. Indeed, this cluster of findings is common in types II, III, and IV hyperlipoproteinemias. Second, by simply looking at a patient's plasma, you can sometimes surmise whether triglycerides ought to be measured. If the plasma is cloudy, the turbidity usually results from one of two things—a recent fatty meal or faulty lipid metabolism. If you allow the plasma to sit at 4C for 24 hours, exogenous triglycerides (chylomicrons) will form a creamy layer on top. Endogenous molecules will be distributed homogeneously.

Painful night leg cramps...

unwelcome bedfellow for any patient–including those with arthritis, diabetes or PVD

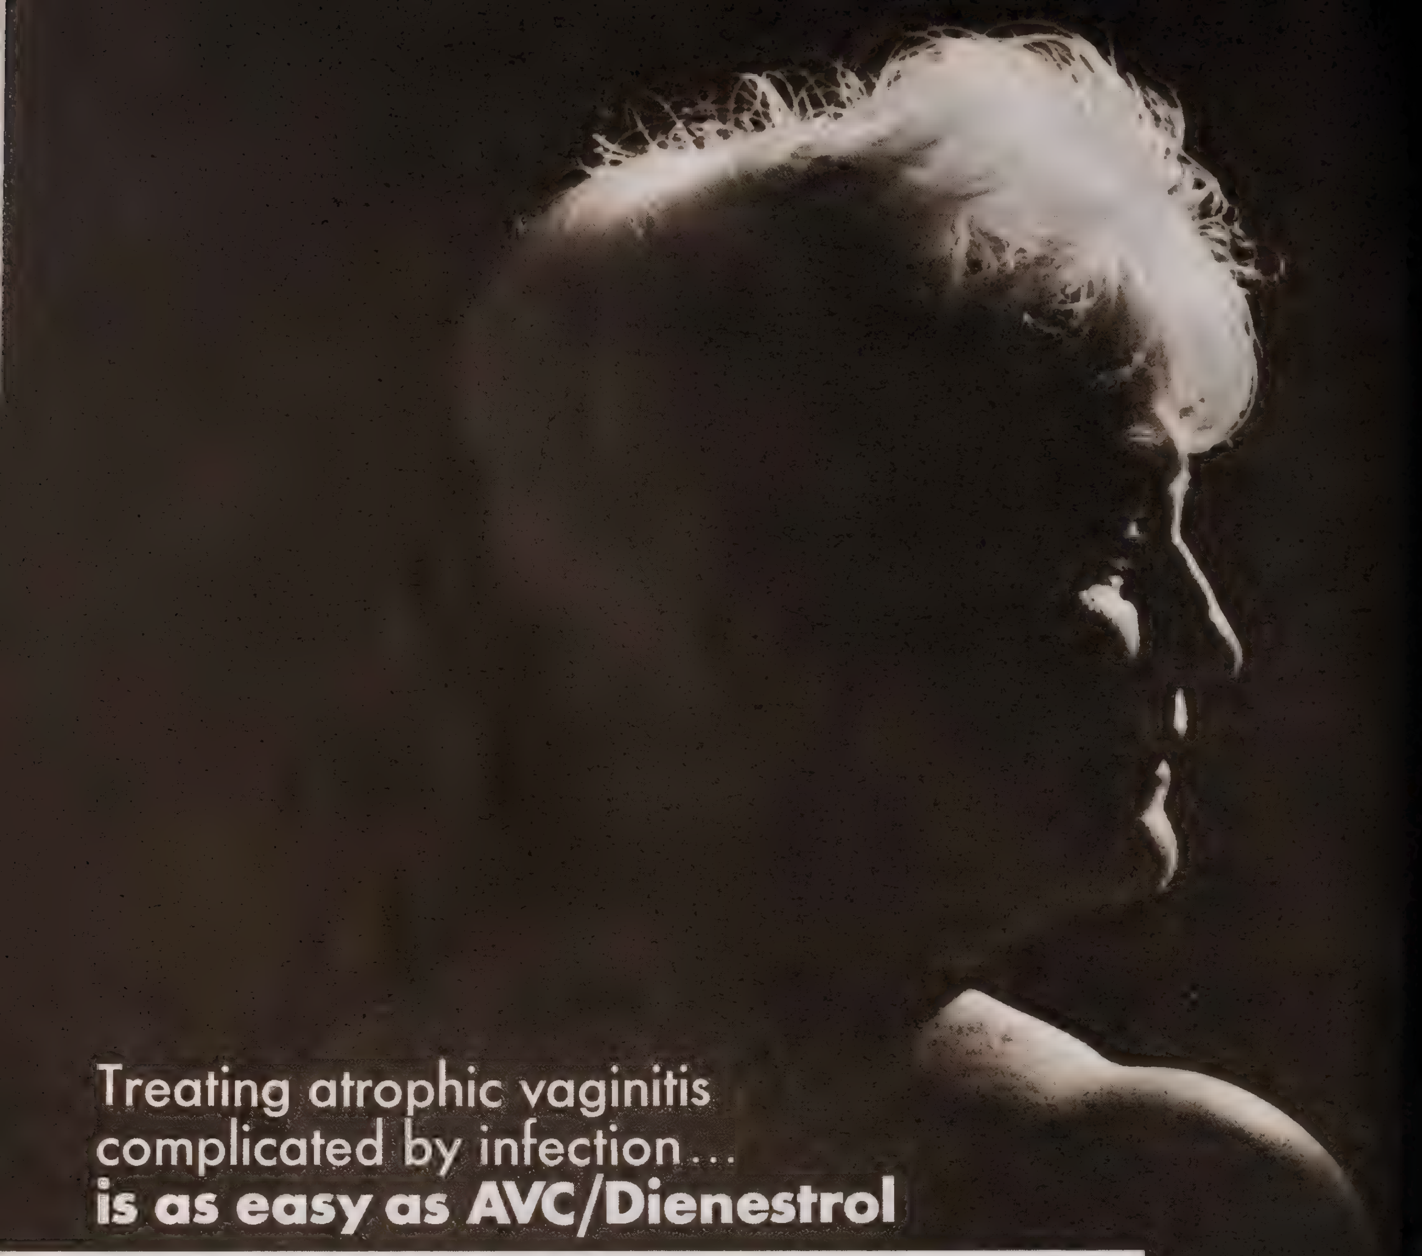
One thing patients can sleep without, particularly patients with chronic disease conditions such as arthritis, diabetes or PVD, is painful night leg cramps. Although seldom the presenting complaint, night leg cramps can tie your patients up in painful knots. Now, just one tablet of QUINAMM at bedtime can usually bring an end to shattered sleep and needless suffering. Your patients will sleep restfully—gratefully—with QUINAMM, specific therapy to prevent painful night leg cramps.

Prescribing Information — Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON-MERRELL INC.
PHILADELPHIA, PENNSYLVANIA 19144

Quinamm™ Specific therapy for night leg cramps

(quinine sulfate 260 mg., aminophylline 195 mg.)



Treating atrophic vaginitis
complicated by infection...
is as easy as AVC/Dienestrol

Dienestrol helps restore estrogen-deficient vaginal mucosa.
It is the *particular* ingredient in AVC/Dienestrol that improves cell maturation counts[1,2] — helps stimulate the restoration of normal vaginal epithelium to resist infection.

Two recent studies reconfirm AVC/Dienestrol efficacy.[1,2] AVC/Dienestrol is proven effective against monilial, trichomonal, nonspecific bacterial vaginitis, and mixed infections.[1,2] AVC/Dienestrol combats infection, helps restore tissue resistance to reinfection.

So even in complex cases, the treatment can remain the same. Comprehensive. Effective. Easy as AVC/D.

Contraindications: Known sensitivity to sulfonamides; diagnosis or familial history of carcinoma of the genital tract or breasts; precarcinomatous lesions of the vagina or vulva; palpable uterine fibromyoma; mammary fibroadenoma; depressed liver function.

Precautions/Adverse Reactions: The usual precautions for topical and systemic sulfonamides should be observed because of the possibility of absorption. Burning, increased local discomfort, skin rash, urticaria or other manifestations of sulfonamide toxicity or sensitivity are reasons to discontinue treatment. The use of AVC/Dienestrol does not preclude the necessity for careful diagnostic measures to eliminate the possibility of neoplasia of the vulva or vagina. Manifestations of excessive estrogenic stimulation through dienestrol absorption may occur. These include uterine bleeding, breast tenderness, exacerbation of menstrual irregularity and provocation of serious bleeding in women sterilized because of endometriosis. Endometrial withdrawal bleeding may occur if use is suddenly discontinued.

Dosage: One applicatorful or one suppository intravaginally once or twice daily.

Supplied: 'AVC/Dienestrol Cream' — Four ounce tube *with* applicator. 'AVC' and 'AVC/Dienestrol Suppositories' — Box of 12 *with* applicator.

Etiology of Allergic Bronchial Asthma*

MALCOLM N. BLUMENTHAL, M.D.†
Minneapolis, Minnesota

ASTHMA COMES from the Greek word meaning gasping or panting. It has thus been defined as that type of dyspnea produced by reversible, paroxysmal, generalized narrowing of the bronchiolar lumina.[1] Though most people feel they can easily recognize and diagnose correctly the condition commonly termed bronchial asthma, there is still much misunderstanding and confusion regarding the exact criteria necessary for the proper diagnosis.

There are two opposing groups with regard to what asthma is. The first believe that all that wheezes is not asthma. They insist that bronchial asthma is a disease initiated by an allergic mechanism which leads to the characteristic pathophysiology and symptoms. All other conditions which may produce identical pictures must not be termed bronchial asthma.[2]

At the other end of the spectrum is the group which states that all that wheezes is asthma. They prefer to indicate that the shortness of breath with cough, expectoration and wheezing caused by bronchospasm, edema and secretion, no matter what the underlying cause, is bronchial asthma.[3] In effect this group claims that asthma is a symptom or syndrome rather than a specific disease. Causes may be allergic, infectious, irritant or emotional, to mention a few.

Incidence of Bronchial Asthma

It has been estimated that about 0.5% of the general population will develop bronchial asthma. This is comparable to the statistics indicating that approximately 10% of the population will have atopy.‡ Bronchial asthma occurs all over the world and in all races. Eskimos and full-blooded Indians are said to have a low incidence. This could be due to a lack of asthma-consciousness among the investigators. There is little difference in the incidence of asthma between the sexes. Males predominate in the first decade of life and after the age of fifty; in the years between there may be a slight predominance of females. The disease may occur at any age. About one third of all cases of bronchial asthma on an allergic basis are said to develop during the first decade of life and probably over three fourths of them are seen before the age of 35. All evidence seems to indicate that social and economic status have no bearing on the incidence of asthma.[4,5]

Pathophysiology of Bronchial Asthma

The main symptoms in asthma are shortness of breath, wheezing, and cough. These result from the primary pathophysiologic processes: the bronchospasm, edema and tenacious secretions. Secondary consequences which may occur include dehydration, abnormal distribution of gas, hypoxia, hypercapnea, and increased work of breathing. Tertiary sequelae include right heart failure, infection, pneumothorax and atelectasis. The final clinical picture in allergic bronchial asthma is dependent upon the various pathophysiologic processes occurring and their consequences.[6]

Sequence of Events Leading To Bronchial Asthma

The sequence of events in allergic bronchial asthma leading to the above pathophysiologic changes has not been completely explained. It is thought that there must first exist the so-called "allergic state." This is a state in which these particular individuals are more likely to have symptoms of allergy than do others under exactly the same conditions. It is the soil in which allergy, in the usual sense, can flourish.

Sensitization

These people with the allergic state have the ability to become sensitized. What forces determine which patient becomes sensitive and which one does not are still unknown. Most likely, hereditary and environmental factors are of primary importance. A review of the statistical data on the familial incidence of allergic disease in asthmatics reveals that 40 to 70 per cent of them give a family history of allergy.[4] Several extensive attempts have been made to define the mode of inheritance of atopy, but the results have been conflicting.[4,7,8] There are several possible explanations for these discrepancies. First, there is no agreement with regard to the criteria of diagnosing atopy. Second, environmental factors may obscure the underlying genetic pattern. Finally, there may be multiple points at which genetic control could be exercised regarding susceptibility to the development of allergic bronchial asthma.[9] Examples of this might include the control of pollen allergens crossing the mucosal barrier of the respiratory tract, differences in antibody production, capacity of antibodies to enter into relationship to the antigen on the target organ, and responses to mediating substances. All of these could be under separate genetic control. Therefore, depending upon the frequency of the genes involved and the exposure to the allergen, a variety of genetic patterns may be encountered. The data on hand seem to indicate that there are genetic factors involved in the development of allergic bronchial asthma, although the exact mode is not clear.

Route of Entry

Environmental factors are of obvious importance regarding the initial exposure of the individual to sufficient allergic substances which produce sensitization. Allergens may enter the tissue by several different routes, including the respiratory system, gastrointestinal tract, skin, and by injection. The chief factors which influence the nature of the response in man include the antigen itself, the duration and intensity of exposure and the route by which the antigen enters. Farmers are exposed to pollen and animal dander in larger amounts than most urban dwellers. Workers in industries such as grain mills and resin factories are exposed to potent allergens normally not contacted by the general population.

The climate may also influence the allergic state. The antigens to which an individual is exposed will depend upon the vegetation which grows in his particular environment. In general, only those plants which are wind-pollinated and produce large amounts of buoyant, windborne pollens are important in the causation of allergic bronchial asthma. Plants such as flowers with strong odors are adapted to insect pollination and thus produce a relatively small amount of sticky heavy pollen;

hence they rarely cause bronchial asthma.[5]

Formation of antibodies

As we have already established, when an allergic person is re-exposed to an allergen which is not antigenic to others, he will respond with the production of specific antibodies. Reagin or skin-sensitizing antibodies are thought to be the main immunoglobulin involved. They are found in vascular and non-vascular fluid.[10] The relationship between circulating reagin and that found in the secretions is not clear. It may be that the antibodies occurring in secretions which are most likely involved in bronchial asthma are not derived from those produced in other parts of the body by plasma cells or lymphocytes and then go to the lung tissue. Rather, it is more likely that the antibodies are synthesized by plasma cells lying just below the epithelial cells of the respiratory tract.[11] These reaginic antibodies have been characterized by Ishizaka as associated with the IGE immunoglobulin.[12] Recent work by Johansson has confirmed these observations.[13,14]

Re-exposure Causing Antigen-Antibody Reaction

Although re-exposure to the specific antigen which the individual is sensitized to can come by any route, the respiratory tract is the most common in bronchial asthma. The location of the antigen-antibody reaction, though not definitely known, may be in the secretions, on the cells, or in the cells. Work by Ishizaka[11] and Tamaszi[12] has shown that in allergic persons ragweed antibodies are present in the external secretions.

Release of Intermediate Mediating Substances

The union of antigen with antibody is thought to produce the clinical picture of bronchial asthma either directly (through irritation or precipitation or changes in the cell enzyme) or indirectly (through the release of intermediate chemical products which in turn act on the lung tissue to cause bronchospasm, capillary dilation with edema and increased secretion). Although it has been demonstrated that the antigen-antibody complex *per se* has produced bronchospasm in non-sensitized tissues, it is felt by the majority that the actual manifestations of asthma are probably due to the action of the mediators at a secondary site, usually smooth muscle, glandular tissue and vascular tissue. The main mediating substances are thought to be histamine, slow-reacting substance, plasma kinin and serotonin. There is a sparsity in the literature of good data on the pharmacology of bronchial asthma. This is due in part to the marked differences between man and the lower animals with regard to the mediating substances.

Histamine

Histamine in man has been demonstrated to cause pruritis, skin erythema, a slight reduction in blood pressure, edema and, at times, generalized angioneurotic edema. In normal subjects, there is usually a complete absence of bronchospasm and severe hypotension using physiologic doses.[14] Nebulization with histamine in a non-atopic individual will cause evidence of bronchospasm; but the threshold is much higher than that for the patient with asthma.[15] Pre-treatment with antihistamines will prevent the formation of these histamine-caused symptoms. Histamine has been released *in vitro* from lung tissue of allergic individuals.[16] Antihistamines usually are not effective in combating the symptoms of allergic bronchial asthma. Histamines alone, therefore, account for only a limited number of the manifestations of bronchial asthma.

Slow Reacting Substance

A slow-reacting substance of unknown composition can cause a relatively slow contraction of smooth muscle. Antihistamines do not antagonize its action. It has been found in lung tissues of pollen-sensitive individuals. Human bronchiolar tissue, according to some investigators, is very responsive to it. Slow-reacting substance administered by aerosol has a bronchoconstricting action in asthmatic patients but has no such effect in normal subjects.[15]

Plasma Kinins

Plasma kinins, one of the many physiologically active polypeptides, have been thought to play an important role in bronchial asthma. They stimulate smooth muscle, cause vasodilation, increased capillary permeability, enhance the migration of leukocytes and stimulate pain fibers. Upon intravenous administration both kallidin I and II increase the resistance of the lungs of anesthetized guinea pigs to inflation. This bronchoconstrictor activity is antagonized by analgesics such as acetylsalicylic acid. Kallidin I by aerosol has no bronchoconstrictor effect in the guinea pig or in normal man. It does, however, initiate bronchoconstriction in the asthmatic patient. There is evidence that a physiologic role of kallikrein is the causation of vasodilation in glands, possibly leading to an increase in their secretions.[15]

Serotonin does not seem to be involved in the production of bronchial asthma in man.[15]

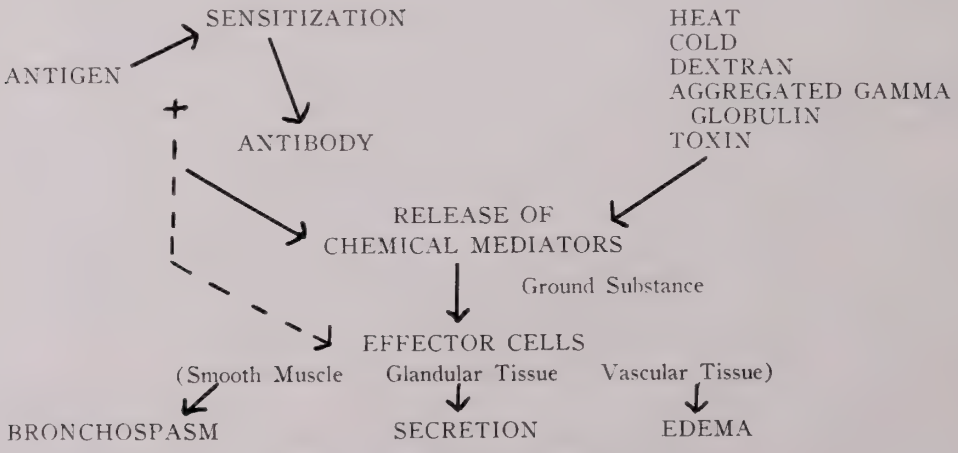
Effect of the Mediating Substances on the Tissue Structures

The mediating substances are thought to act on the tissue structure causing bronchospasm, edema of the mucosa and increased mucus. This in turn results in the clinical picture of bronchial asthma characterized by cough, shortness of breath, and wheezing. It is apparent that bronchial asthma is distinguished not only by the release of active substances but also by the exaggerated response of the bronchial tree to the chemical mediators. A number of reports have demonstrated that the respiratory tract in patients with asthma is overly sensitive to the actions of inhaled histamine, acetylcholine, slow-reacting substance and bradykinin.[16] Whether this heightened reactivity is due to some special property of the capillaries, mucous glands, smooth muscle or some other structure in the asthmatic lung or whether it is a cause or effect of bronchial asthma is unknown.

It is evident, however, that the mediators, once they are released or formed as a result of the antigen-antibody interaction, must travel through a finite intercellular space before reaching the effector cell. It has been suggested that the chemical characteristics of the intercellular space and the ground substance filling it are of primary importance in determining the activity of these chemicals on the effector cells.[16] Therefore the chemical pathology of asthma may involve the ground substance rather than a unique cell responsiveness.

Many have investigated the importance of the autonomic nervous system and the acetylcholine-cholinesterase system in bronchial asthma. It has been suggested that asthma may in part result from a functional imbalance between the alpha and beta receptors in the lung. Conflicting evidence seems to indicate that there is a decreased response with regard to the beta receptors.[17,18] Its importance in the clinical disease or whether it is a cause or effect of the condition has yet to be determined.

The importance of the acetylcholine-cholinesterase system has been stressed in the past. Many investigators feel that asthma is a disease of dysautonomia, suggesting that it represents



Figure—Etiology of Bronchial Asthma

a state of parasympathetic preponderance. Threshold doses of acetylcholine to produce bronchoconstriction were less in asthmatics than in normal subjects. Scattered reports of elevated levels of acetylcholine in patients with asthma have been published.[16]

Although the exact mechanism present in the production of the symptoms of bronchial asthma on an allergic basis is not known one can postulate essentially two main steps (Figure). First is the presence of an immunologic reaction characterized by sensitization with the production of antibodies followed by an antigen-antibody reaction. Next is the selectivity of the tissue which will react as the result of the antigen-antibody union. The finding that symptoms of bronchial asthma can occur without the presence of known antigens lends support to the concept that the antigen-antibody interaction activates a nonstable enzyme which in turn activates a mediating substance. Other factors have been shown to produce the same activation or release of mediating substances. Among these are heat and cold, low molecular compounds such as 48/80, and basic amines and high molecular substances such as dextran, endotoxin, aggregated gamma globulin and proteolytic enzymes.[15,19] Hence, one can say that all allergic asthma is due to a mediating substance being released. But not all mediating substances which are released can be traced to an antigen-antibody union.

Role of Allergens in the Causation of Allergic Bronchial Asthma

Allergens are the antigens which upon reintroduction cause pathological tissue reactivity or hypersensitivity. These allergens may attack different shock tissues and produce various clinical manifestations. Therefore the same allergen may cause asthma, hives, and a contact dermatitis in the same person.

It should be stressed that the allergens may be multiple and usually are. Also, allergens may be only part of the whole picture and may be greatly influenced by other factors. As pointed out, the allergic state is influenced by inherent predisposition, by exposure to allergic substances adequate to stimulate antibodies, and by yet unknown factors. This basic allergic state plus the exciting causes such as an extrinsic allergen like pollen and non-specific factors such as emotional state and fatigue are all factors which determine the type and degree of clinical picture.

Some persons are so highly sensitive to an allergen that even the smallest amount will produce symptoms. Others may tolerate small amounts but develop symptoms if exposed to larger quantities. Thus the allergic symptoms may be minimal, due to a balance state between the tolerance of the patient on the one hand, and the allergic and sensitized state and slight exposure. Tolerance may be outweighed by excessive exposure to the allergen; then clinical symptoms may result. Finally, despite slight exposure to the allergen, the allergic equilibrium may be disturbed by non-specific precipitating causes such as heat, cold, infection, psychic trauma and irritation.

Summary

Allergic bronchial asthma may be defined as a symptom complex in which there are paroxysms of reversible airway obstruction manifested as wheezing and dyspnea, triggered off by an allergen to which the person had been previously sensitized. As a result an immunologic reaction occurs with the release of mediating substances which in turn cause the primary pathophysiologic processes of edema, bronchospasm and secretions. There seems to be an increased sensitivity to the mediating substances in these patients. It should be stressed that in allergic patients with asthma, more than allergic factors need to be considered in its etiology. We must remember that allergic patients may have all other diseases that we are all heir to, and these may be the most important. Beyond that, non-specific factors may initiate, aggravate and complicate allergic bronchial asthma. Cold air, chemical irritation, high humidity, respiratory tract infection, and psychogenic factors are all examples of predisposing, complicating and precipitating factors. Their role in the causation of allergic bronchial asthma is often just as important as that of the specific allergen.

Valium® (diazepam) *t.i.d.* and *h.s.*

M. A. (class of '66)…Ph.D. (thesis, in progress)…letters that represent a young lifetime of work…a formal education nearing completion. But there are still long, arduous examinations to pass, a doctoral thesis to finish…a period in which stress is often converted into the gastrointestinal symptoms of psychic tension. For this kind of patient—with no demonstrable pathology—consider the usefulness of Valium (diazepam).

Valium can help relieve psychic tension and resultant somatic symptoms, within the first day for some patients. Valium is also useful in psychic tension with associated depressive symptoms. And Valium can help relieve psychic tension-induced insomnia with an *h.s.* dose added to the *t.i.d.* schedule.

Valium is generally well tolerated. In proper maintenance dosage it seldom dulls the senses or interferes with functioning. Side effects most commonly reported have been drowsiness, fatigue and ataxia.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Valium® (diazepam)

2-mg, 5-mg, 10-mg tablets
to help relieve psychic tension
and its somatic symptoms

Federal Programs for Pulmonary Diseases

The purpose of this presentation is to assemble the concepts of "how to treat patients," "what kinds of patients you may have," and "what possible difficulties in diagnoses," and then relate these to the fact that you as a physician are a part of a community.

The Public Health Service in the last few years has developed what we consider a reasonable concept of looking at the patient and his community, and particularly the patient with a chronic illness. We call this a "Comprehensive Care Wheel."

We feel that the center of concern for any person in the health profession is the patient and his family, and that any health professional who sees a patient must think of *four areas.* He must look at the *physical,* the *psychological,* the *economic* and the *social* aspects of the problem. That, of course, doesn't mean that he treats all of them; but as a health professional he is required to consider these four areas no matter who the patient or the family may be. Then there must be some kind of *evaluation.* Possibly not by the health professional who made the original contact with the patient and his family; but there must be an evaluation and a *referral.* We feel that every community in the United States can divide its medical care services into three possible kinds of referrals. First, there is the classic in-patient referral that puts the person into the hospital or a medical treatment situation, nursing home, hospital, or a specialized hospital of some kind.

The second is an out-patient referral which requires an out-patient clinic that may be free standing. Also included in this concept is the private practitioner's office which is a kind of out-patient service, for when the patient comes, the diagnosis and treatment outline is made and he may then be asked to return unless he is placed in an in-patient treatment system.

Finally, there is the possibility of home care, and in this area we are just beginning to have services available in most communities. I don't know why it has taken us so long to get back to the old-fashioned way of taking care of people, i.e., keeping them in the home so that they can have around them the people that will give them the emotional support and help to recover from the shock of illness. Fortunately we are now developing services that can be dispensed from a central in-patient or out-patient building or taken into the home.

For instance, a community must provide *personnel* of some kind. (Most of us are provided by the community.) There must be *some funds and some facilities* from the community; otherwise there will be no medical services of any dimension. There must also be *research and training* provided by the community, and finally, some *coordination and administration,* or at least some plan therefor if this *care* wheel is to function in any community.

Congenital Cardiac Disease*

Causal Factor in Pediatric Pulmonary Disease

RUSSELL V. LUCAS, JR., M.D.†
Minneapolis, Minnesota

CHILDREN WITH CONGENITAL cardiac disease have frequent pulmonary complications which contribute a significant limiting factor in successful management of these infants. Approximately 50% of children born with congenital heart disease die within the first year of life.

Cardiac disease influences all components of the respiratory system through a variety of etiologic mechanisms as outlined in the Table.

Alterations in the Pulmonary Vascular Bed

Understanding of the effects of cardiac disease on the pulmonary vascular bed is enhanced by an appreciation of the normal maturation of the pulmonary vessels. During fetal life and at the moment of birth, pulmonary arteriolar resistance is equivalent to systemic arteriolar resistance as a consequence of thick-walled, narrow-lumened pulmonary arterioles[1,2,3] (Figure 1, *left*). Pulmonary vascular resistance drops significantly in the

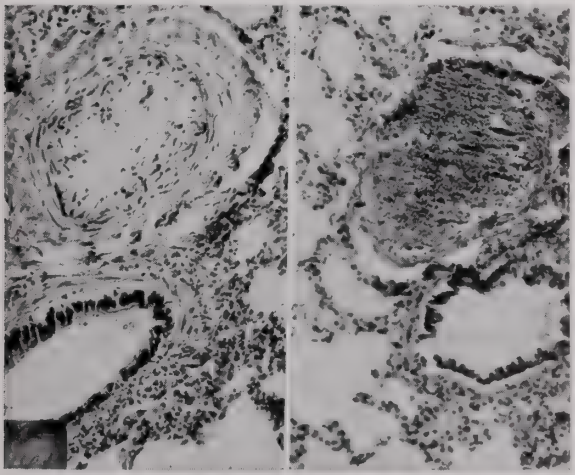

Fig. 1—Maturation of the Pulmonary Arteriole. *Left*: A small pulmonary arteriole in a newborn infant without cardiac or pulmonary disease. The thick-walled media is apparent. *Right*: A comparable pulmonary arteriole in a five-year-old child. Note the marked decrease in the thickness of the media. Small bronchioles confirm the comparable size and magnification of these pulmonary arterioles. Hematoxylin and eosin X135.

†Paul F. and Faith S. Dwan Professors of Pediatric Cardiology, University of Minnesota.

first few hours after birth; however, it remains above normal "adult" values because the pulmonary arteriolar media remains thick. It decreases in size gradually over the next six months and is accompanied by a fall in the pulmonary vascular resistance (Figure 1 *right* and Figure 2).

The congenital cardiac lesions discussed below may alter normal pulmonary vascular maturation in the following ways: (1) Maturation may be prevented; (2) Maturation may be delayed; (3) *Medial* hypertrophy and intimal proliferation may be superimposed at any point in the maturational process.

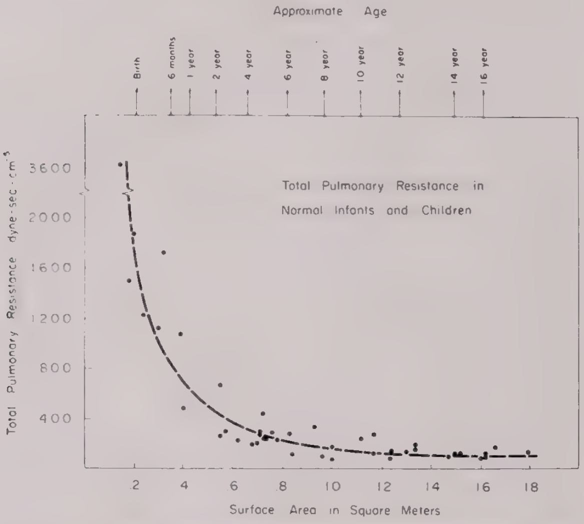

Fig. 2—Total pulmonary resistence as calculated from cardiac catheterization data in normal infants and children. Adapted from Lucas and associates.[3]

Obstruction to Pulmonary Venous Drainage

A classical example of pulmonary venous obstruction is mitral stenosis (Figure 3). Other responsible congenital defects include cor triatriatum, stenosis of individual pulmonary veins, supravalvular stenosing ring of the left atrium, total anomalous pulmonary venous connection with obstruction, mitral insufficiency, and any cause of left ventricular failure.[4] The common denominator of these left-sided obstructive lesions is elevated pressure in the pulmonary veins. The wall of the hypertensive pulmonary vein exhibits medial hypertrophy (Figure 4).

There are two major protective mechanisms which operate when pulmonary edema threatens life. The first is increased pulmonary lymphatic flow which has been demonstrated experimentally[5] and for which there is clear anatomic evidence of the form of gross dilatation of pulmonary lymphatics[6] (Figure 5). The second protective mechanism to minimize pulmonary edema is reflex constriction of the pulmonary arterioles (Figure 6). This results in a decrease in blood flow to the lungs until input and output are balanced. Pulmonary arteriolar constriction causes pulmonary hypertension, right ventricular hypertrophy, and

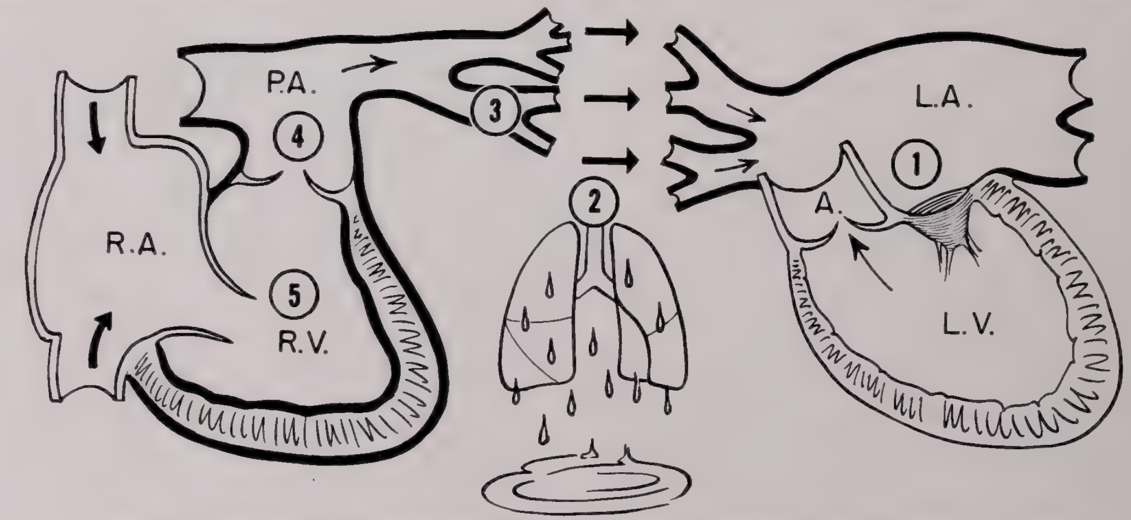

Fig. 3—Diagrammatic representation of hemodynamics in congenital mitral stenosis. Arrows represent the pulmonary vascular bed. Left atrial pressure is elevated (1) and is freely transmitted to the pulmonary capillary bed. Pulmonary capillary hydrostatic pressure exceeds osmotic pressure and pulmonary edema occurs (2). A compensatory mechanism to prevent pulmonary edema in constriction of pulmonary arterioles (3) which results in pulmonary hypertension (4) and may lead to right heart failure (5). From Lucas and Schmidt, Congenital Heart Disease in "Current Diagnosis", edited by Conn, Clohecy and Conn, W. B. Saunders Company, 1966. Reproduced by permission of the publishers.

in time right heart failure. Thus pulmonary venous obstruction profoundly alters the function of the pulmonary vascular bed and also results in intrinsic and extrinsic airway obstruction as will be discussed below.

Correction of the anatomic lesion producing pulmonary venous obstruction almost invariably results in return of the pulmonary vascular bed to normal and thus a normal hemodynamic state.

Increased Pulmonary Blood Flow, Normal Pulmonary Artery Pressure

The classic example of this hemodynamic situation is atrial septal defect. Other responsible defects include partial anomalous pulmonary venous connection, small ventricular septal defect and small patent ductus arteriosus. Maturation of the pulmonary vascular bed proceeds normally. At varying ages, but usually in the third or fourth decade of life, intimal proliferation occurs in the pulmonary arteriole. Resistance to pulmonary blood flow increases, pulmonary artery pressure rises, and the proliferative process progresses at an accelerating rate. As a consequence, the left to right shunt becomes balanced, then reverses. Symptoms of cor pulmonale appear and right heart failure may supervene. Intimal proliferation is not a reversible process. If it has progressed to the point of balancing the shunt, the pulmonary obstruction is then the factor limiting effective cardiac output. Repair of the cardiac defect is of no benefit in this circumstance.

Increased Pulmonary Blood Flow, Elevated Pulmonary Artery Pressure

The common cause is large ventricular sep-

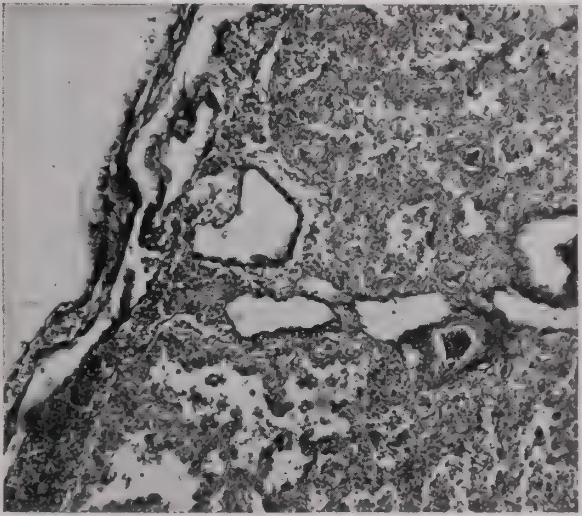

Fig. 5—Gross dilatation of pulmonary lymphatics in a child with pulmonary venous obstruction. The large dilated irregular lymphatic channels are seen under the pleura and in an interlobular septum. Hematoxylin and eosin X 25. From Lucas and Associates.[6] Reproduced by permission of the American Academy of Pediatrics, Inc.

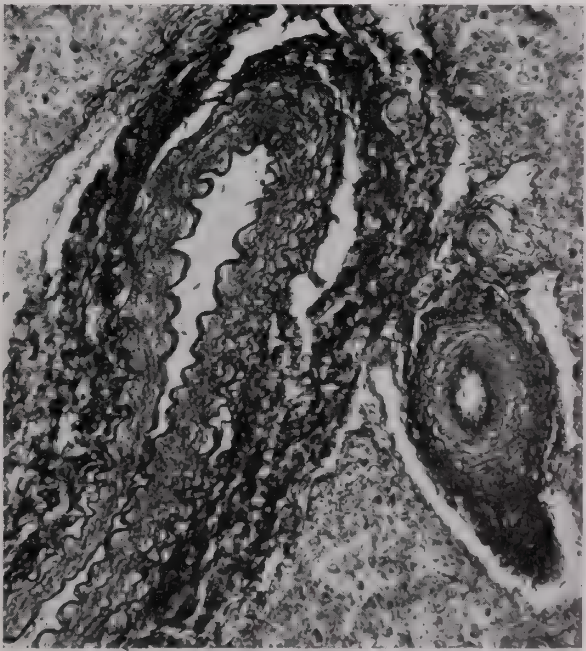

Fig. 6—Medial hypertrophy of pulmonary arterial vessels in a four-and-one-half-month-old child with pulmonary venous obstruction. There is medial hypertrophy of the large elastic artery, medium-sized muscular artery and several small arterioles. Elastic tissue stain X 135.

tal defect. Other defects resulting in this hemodynamic state are large patent ductus arteriosus, aortico-pulmonary window, truncus arteriosus, transposition of great vessels with ventricular septal defect, origin of both great vessels from the right ventricle without pulmonary stenosis, and single ventricle without pulmonary stenosis. Despite the similar hemodynamic stress, several different adaptations of the pulmonary vascular bed have been recognized.[7] Pulmonary vascular maturation may fail to occur; the high fetal pulmonary vascular resistance is maintained and pulmonary blood flow is minimized. Delayed maturation of the pulmonary vascular bed is a second response; pulmonary vascular resistance falls gradually, allowing adjustment of the hemodynamic system to increasing pulmonary blood flow. Pulmonary vascular bed maturation may also occur normally. This response allows massive pulmonary blood flow and is usually accompanied by severe congestive heart failure. In these latter patients, secondary medial hypertrophy usually develops.

As long as the alteration in the pulmonary arteriole is limited to hypertrophy of the media (Figure 7, left) the process is reversible, and surgical correction of the cardiac defect allows the pulmonary vascular bed to return to normal. On the other hand, intimal proliferation (Figure 7, right) is an irreversible phenomenon. Should this process progress to the point whereby the shunt is balanced, the irreversible pulmonary vascular lesions represent the limiting hemodynamic factor and cardiac surgery is of no benefit. These irreversible intimal changes may develop as early as the first year or as late as the third decade of life.

The differing responses of the pulmonary vascular bed to the similar stresses of high pulmonary blood flow and increased pulmonary pressure are presumably related to variability of pulmonary vascular reactivity in man.

Thrombotic and Embolic Complications

Bacterial Endocarditis

Patients with congenital cardiac disease have

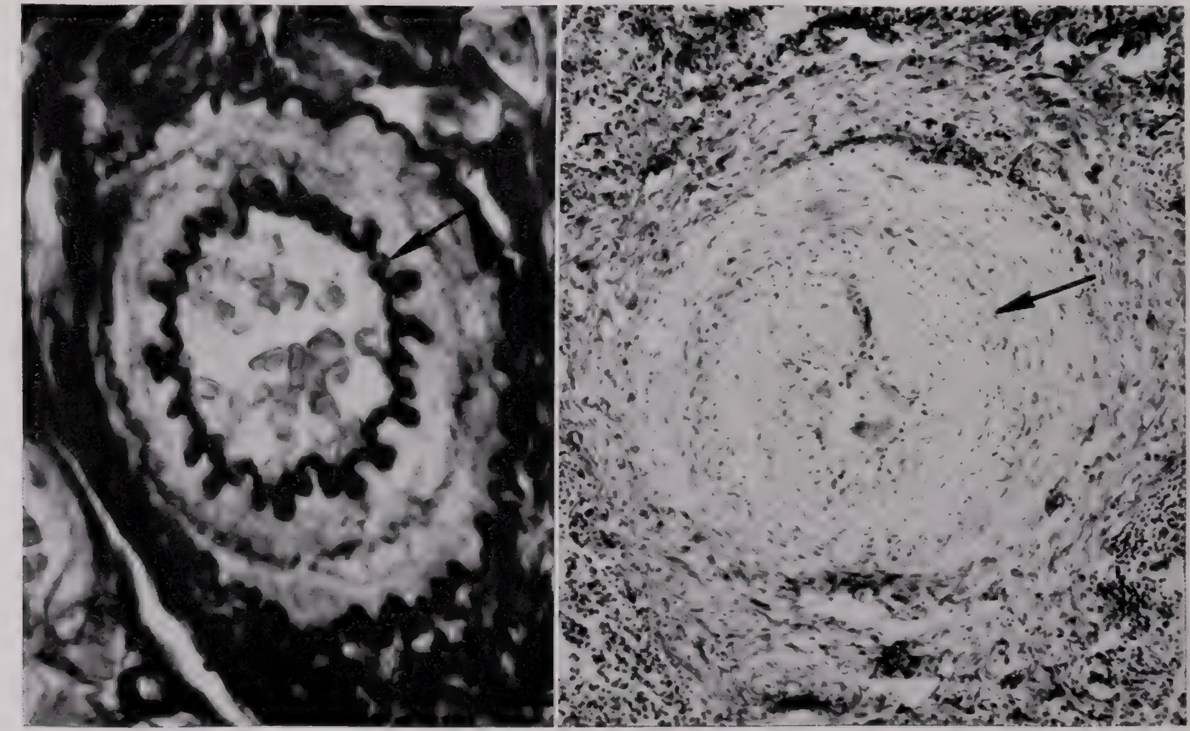

Fig. 7—Medial hypertrophy and intimal proliferation in the pulmonary arteriole in two patients with ventricular septal defect. The intimal elastic lamina (arrows) separates intima from media. *Left.* Pulmonary arteriole in a 20-month-old boy. Note significant medial hypertrophy and absence of intimal proliferation. Elastic tissue stain. *Right.* Pulmonary arteriole in a five-year-old boy. In addition to medial hypertrophy there is prominent intimal proliferation. Hematoxylin and eosin.

a predisposition to bacterial endocarditis; in patients with acquired valve disease endocarditis almost always involves a left-sided cardiac valve. On the other hand, bacterial endocarditis in congenital heart disease involves a right-sided valve or structure in the majority of cases. Thus, in congenital heart disease, when septic emboli occur they most often go to the lung. While these septic emboli may produce subtle pulmonary changes, they have not been incriminated as a cause for demonstrable permanent pulmonary disease. Our recent experience suggests that bacterial endocarditis may be a cause of significant, permanent pulmonary disability and is more common than appreciated. In the last year we have seen two patients with tetralogy of Fallot and bacterial endocarditis involving the right ventricular outflow tract who developed permanent and complete obstruction of the left pulmonary artery. The following case illustrates this complication of bacterial endocarditis.

Case Report

A nine-year-old girl with mild tetralogy of Fallot was admitted to the hospital six weeks after undergoing dental work. Six blood cultures grew Streptococcus viridans. A chest x-ray revealed an infiltrate in the left lung field which progressed to a wedge-shaped lesion extending to the surface of the lung (Figure 8). The bacterial endocarditis responded to penicillin therapy and a bacteriologic cure was achieved and maintained. At that time a lung scan (radioactive macro-aggregated albumin) revealed no evidence of blood flow to the left lung (Figure 9). Pulmonary arteriography was then performed and confirmed the absence of blood flow to the left lung. (Previous angiography had demonstrated a normal left pulmonary artery and normal blood flow to the left lung.) (Figure 10).

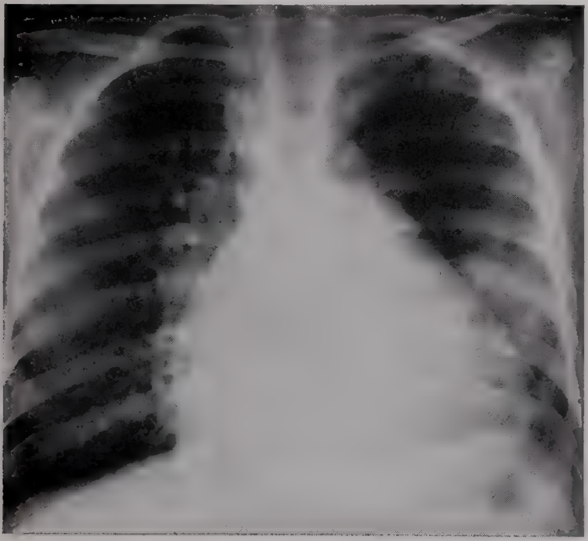

Fig. 8—Thoracic roentgenogram in a nine-year-old girl with tetralogy of Fallot, bacterial endocarditis and pulmonary embolus in the left lung. Note the wedge-shaped opacity extending to the pleural surface in the midleft lung field.

Correction of the intracardiac defect was performed without complication. The patient continues to have significant exercise intolerance. The left lung is non-functional.

Thrombosis Secondary To Decreased Pulmonary Blood Flow

When total pulmonary blood flow is diminished, velocity of blood flow through the lungs is decreased. Polycythemia, secondary to arterial desaturation, is also usual. As a result of these and possibly other factors, thrombosis may occur in pulmonary vessels. An occasional patient with tetralogy of Fallot is so affected. In these patients the pulmonary vascular obstruction may not be apparent preoperatively since pulmonary blood flow is low. When the vascular obstruction is unmasked by corrective surgery, adequate pulmonary blood flow is not attainable and pulmonary hypertension and right heart failure may follow.

Anatomic Features Resulting in Airway Obstruction

In infants with congenital cardiac disease emphysema and atelectasis as a result of airway obstruction are commonly seen. In these

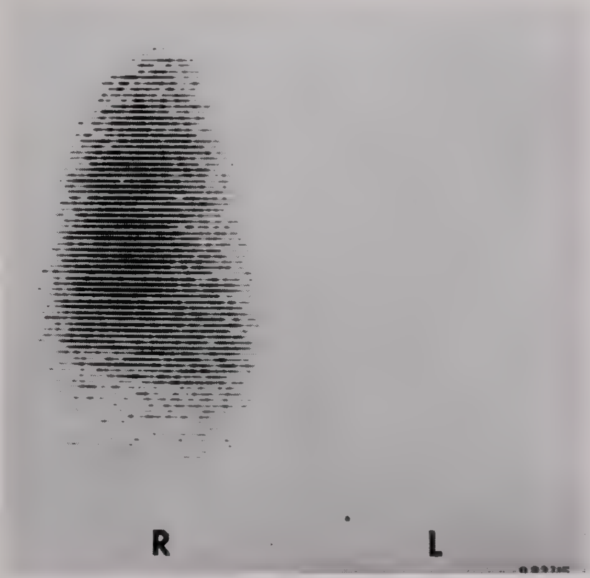

Fig. 9—Lung scan four weeks following the roentgenogram depicted in Figure 8. There is no evidence of blood flow to the left lung (L). The scan of the right lung (R) appears normal.

patients airway obstruction may be due to compression of the bronchi by adjacent structures or by intraluminal bronchial narrowing, or by both.[8]

Airway Obstruction Caused by External Compression

External bronchial compression is most often the result of distended, hypertensive pulmonary arteries. Pulmonary hypertension may be a manifestation of certain left-to-right shunts or of pulmonary venous obstruction. The relationships of the pulmonary arteries to the main stem bronchi are seen in Figure 11. As the left pulmonary artery crosses the left main stem bronchus from front to back it may compress the superior aspect of the left main stem bronchus. In addition, the left upper bronchus may be compressed by the inelastic C-shaped arterial structure formed by the branch of the pulmonary artery leading to the left lower lobe as it crosses behind the left upper bronchus and then descends. A third site which shows a predilection for obstruction is the bronchus intermedius which is compressed as the right pulmonary artery crosses over it from front to back.

Bronchial compression due to enlarged, hypertensive pulmonary arteries is intensified when left atrial enlargement is also associated, since the left atrium lies immediately subjacent to the bronchial bifurcation and its enlargement results in an upward pressure on the inferior aspect of both major bronchi, particularly the left. The pulmonary arteries limit the upward mobility of the bronchi. Thus the bronchi are caught in a hemodynamic vise, the upper jaw consisting of the distended hypertensive pulmonary artery and the lower jaw, the enlarged left atrium.[8]

The cardiac defects resulting in a combination of left atrial enlargement and dilated hypertensive pulmonary arteries include ventricular septal defect, patent ductus arteriosus, atrioventricular canal, transposition of the great vessels and the various causes of pulmonary venous obstruction.

If bronchial obstruction is incomplete, lobar emphysema occurs. More commonly, obstruction is complete and produces atelectasis of the obstructed lobe.

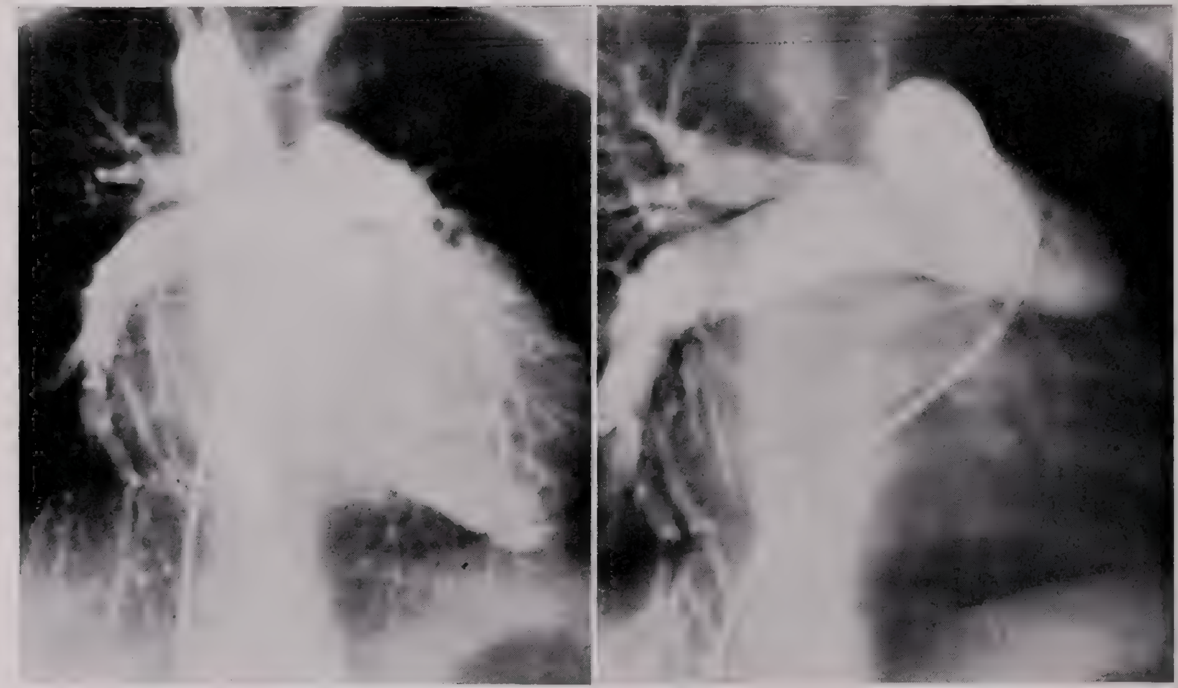

Fig. 10—Angiograms in the patient shown in Figures 7, 8 and 9. *Left:* Right ventriculogram obtained prior to the episode of bacterial endocarditis. There is normal filling of both right and left pulmonary arteries. *Right*: Pulmonary arteriogram obtained subsequent to the bacterial endocarditis and the infiltrative process noted in the left lung. Main pulmonary artery and right pulmonary artery fill normally. There is no opaque dye entering the left pulmonary or the left lung field.

Intrinsic Airway Obstruction

Multiple factors may contribute to intraluminal bronchial narrowing. Since the bronchial veins communicate with the pulmonary venous system, those conditions resulting in elevation of pulmonary venous pressure will also result in bronchial venous hypertension. This in turn leads to increased bronchial secretions and edema of the bronchial mucosa.

Infection is a common complication in patients with increased pulmonary blood flow, atelectasis and congestive cardiac failure. Infection also results in mucosal edema and excessive secretions. When dehydration occurs, a more viscous secretion increases the likelihood for intrinsic obstruction.

These intrinsic factors may be the sole cause of obstruction or may act in conjunction with extrinsic compression of the bronchi to result in a critical decrease in intraluminal diameter.

Predilection of Infants to Pulmonary Complications

The incidence of pulmonary complications in congenital cardiac disease is highest in the first year of life. Alterations in the pulmonary vascular bed contribute to this age incidence.

Other pulmonary factors also favor a high incidence of pulmonary complications in infants. Resistance to air flow through a bronchus is proportional to $1/r^4$ ($r =$ radius of bronchial lumen). Thus, in the infant, the initially small bronchial radius may be reduced to the critical point of obstruction by relatively modest intrinsic or extrinsic forces. As growth occurs, a greater decrease in luminal size is required before the bronchus is obstructed. Secondly, the soft pliable bronchial cartilage in the infant is readily deformed by extrinsic pressure. Finally, the pores of Kohn in the infant are poorly developed. Bronchial obstruction is thus more likely to result in atelectasis since collateral ventilation is prevented.

TABLE

Pulmonary Complications of Congenital Cardiac Disease

- I. Alterations in the Pulmonary Vascular Bed
  - A) Obstruction to pulmonary venous drainage.
  - B) Increased pulmonary blood flow; normal pulmonary artery pressure.
  - C) Increased pulmonary blood flow; increased pulmonary artery pressure.
- II. Thrombotic and Embolic Complications
  - A) Bacterial endocarditis (involving right-sided structures).
  - B) Thrombosis secondary to decreased pulmonary blood flow.
- III. Airway Obstruction
  - A) External bronchial compression.
  - B) Intrinsic bronchial obstruction.

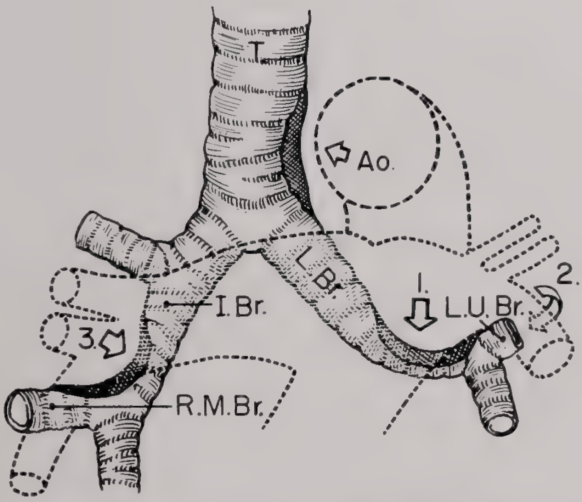

Fig. 11—Sites of bronchial compression due to enlarged, hypertensive pulmonary arteries. The dotted lines represent the more anterior pulmonary arteries. 1) Left pulmonary artery compresses the superior portion of the left bronchus (L. BR.) as it crosses over the bronchus from front to back. 2) The arterial branch to the left lower lobe crosses behind the left upper bronchus (L. U. BR.) before it descends. The left upper bronchus is thus caught in a C-shaped vascular sling and may be obstructed. 3) Right pulmonary artery crosses over the bronchus intermedius (I. BR.) and the artery branches to the right lower lobe cross behind the right middle lobe bronchus (R.M.Br.) Compression of the bronchus intermedius more often results in atelectasis of the right middle lobe; but the right lower lobe may be obstructed as well. The left atrium lies immediately subjacent to the tracheal bifurcation. When the left atrium enlarges, it pushes the bronchi, particularly the left bronchus, upward and intensifies the obstructive effect of the enlarged pulmonary arteries. Ao=aorta. T=trachea. Comment

As the heart and lung are intimately bound together anatomically and hemodynamically so must they be inseparable in our consideration of the child with congenital cardiac disease.

Infants and children with cardiac disease may present with pulmonary problems such as pneumonia, atelectasis, lobar emphysema or what appears to be diffuse bronchiolitis. Thus the differential diagnosis in the infant or child with pulmonary symptoms must include congenital cardiac disease.

Further, successful management of the infant or child with congenital heart disease depends on the early recognition, prompt treatment and, ultimately, prevention of the respiratory complications which are so common. In the infant in particular, pulmonary complications limit our success in preoperative and postoperative management. Every effort must be expended to improve our treatment in the acute respiratory problems encountered in the infant with congenital cardiac disease.

Finally, while we are well aware of the acute respiratory problems in congenital cardiac disease, we know little of the long-term pulmonary sequelae in these patients. The knowledge that intimal proliferation in the pulmonary arteriole is an irreversible process has influenced us to lower the age of operative intervention in a variety of cardiac defects in order to prevent it. However, the long-term sequelae of chronic atelectasis, lobar emphysema, bacterial endocarditis and pulmonary arterial thrombosis are not known. When we acquire better knowledge of these chronic pulmonary processes, further changes in our treatment philosophy in the patients with congenital heart disease may be in order.

Butisol SODIUM®

(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. BUTISOL SODIUM (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

serves no useful
purpose

Rx **Tussionex**®
(Resin complexes of Hydrocodone and Phenyltoloxamine)

...it works
(usually
for 10 to 12
hours*)

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic — oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.

*DOSAGE: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

No place for beginners

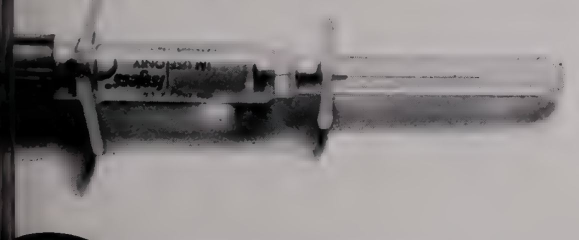
Terramycin®
oxytetracycline)

Fire victim. Examination reveals second degree burn of lower eg. To combat shock, restore circulatory volume and replace protein loss, plasma is administered. Local pressure dressing applied. Limb elevated to limit the flow of lymph. About 36 hours after admission the patient develops an elevated temperature and complains of pain at the site of the lesion. Dressing removed. A suppurating slough area has developed over part of the burn. A swab specimen is taken for culture and the slough area is debrided. Antibacterial treatment is begun with Terramycin I.M. Days later, recovery is progressing, and the laboratory report shows a mixed infection with a predominance of susceptible coliform bacteria, confirming the therapeutic choice. Terramycin therapy is continued until all signs of infection disappear.

Experience has shown that Terramycin offers special advantages in treating bacterial infections complicating burns, when strains of causative organisms are susceptible. Broad-spectrum antibacterial coverage. Activity unaffected by penicillinase. Rapidly achieved therapeutic blood levels. Proven tissue toleration.

Terramycin I.M. is the only preconstituted broad-spectrum antibiotic designed specifically for intramuscular use. Requires no refrigeration. Remains stable for at least two years. Available for immediate use in Isoject,® a disposable injection unit. In difficult as well as routine cases, when tests reveal susceptible organisms, consider Terramycin. One of the world's most widely used broad-spectrums.

Terramycin® I.M.
oxytetracycline)



Pfizer **LABORATORIES DIVISION**
New York, N.Y. 10017

Contraindicated: In individuals hypersensitive to any of the components of this drug.
Warnings: If renal impairment exists, even usual doses may lead to excessive systemic accumulation and possible liver toxicity. In such patients, lower than usual doses are indicated and for prolonged therapy oxytetracycline serum level determinations may be advisable.
Terramycin may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.
Use of oxytetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of teeth. This effect occurs mostly during long-term use of the drug, but it has also been observed in usual short-treatment courses.
During treatment with tetracyclines, individuals susceptible to photodynamic reactions should avoid direct sunlight. Discontinue therapy at first evidence of skin discomfort.
Note: With oxytetracycline, phototoxicity is not believed to occur and photoallergy is very rare.
Precautions: Use of broad-spectrum antibiotics occasionally may result in overgrowth of nonsusceptible organisms. Where such infections occur, discontinue oxytetracycline and institute specific therapy.
As with all intramuscular preparations, Terramycin Intramuscular Solution should be injected well within the body of a relatively large muscle. *Adults:* The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus), or the mid-lateral thigh. *Children:* It is recommended that intramuscular injections be given preferably in the mid-lateral muscles of the thigh. In infants and small children the periphery of the upper outer quadrant of the gluteal region should be used only when necessary, such as in burn patients, in order to minimize the possibility of damage to the sciatic nerve.
The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.
Increased intracranial pressure with bulging fontanelles has been observed occasionally in infants receiving therapeutic doses of the drug, but such signs and symptoms have disappeared rapidly on cessation of treatment with no sequelae.
Adverse Reactions: Subcutaneous and fat-layer injection may produce mild pain and induration which may be relieved by an ice pack. Very mild gastrointestinal disturbances, not requiring discontinuance of the drug, may occur occasionally. Allergic reactions, including anaphylaxis, rarely have been observed.
Dosage: *Adult:* The optimal dosage varies, depending on the type and severity of infection. Unless otherwise specified, a dose of 100 mg. every 8 to 12 hours, or a single daily dose of 250 mg. should be adequate for the treatment of most mild or moderately severe infections. In severe infections, 100 mg. every 6 to 8 hours, or 250 mg. every 12 hours may be necessary.
Serum levels obtained by the recommended dosages are comparable to those provided by the oral dosage of 1 to 2 Gm. daily in adults. Antibiotic therapy should be continued for at least 24 to 48 hours after all symptoms and fever have subsided.
In certain diseases specific courses of therapy may be recommended as a general guide. In primary and secondary syphilis for example, the daily administration of 2 Gm. oxytetracycline, orally, in divided doses for two weeks has given good results. In cases of gonococcal infection two intramuscular injections of 250 mg. each, or one intramuscular injection of 250 mg. combined with one gram given orally as a single dose, will usually suffice, but repetition of this therapy will be required in an occasional case.
In the treatment of hemolytic streptococcal infections, therapy should continue for at least 10 days to prevent development of rheumatic fever or glomerulonephritis. In the treatment of staphylococcal infections indicated surgical procedures should be carried out in all cases.
Pediatric: A dosage of 3 mg./lb./day in two doses has been found satisfactory in the treatment of most mild to moderately severe infections. For more severe infections, higher dosages may be indicated and should be adjusted accordingly.
Terramycin Intramuscular Solution provides maximum absorption and patient toleration with minimal local irritation.
Supply: Terramycin (oxytetracycline) Intramuscular Solution: available in single dose, prescored glass ampules containing 100 or 250 mg. oxytetracycline/2 cc., Isoject® syringes containing 100 or 250 mg. oxytetracycline/2 cc. and 10 cc. multiple dose vials containing 50 mg. oxytetracycline/cc.

EXCELLENT OPPORTUNITY for General Practitioner and General Surgeon to join 5 man general practice group. Services of Radiologist immediately available. Salary open. Liberal fringes with opportunity for early partnership. College town serving population of 22,000, 30 miles from Minneapolis-St. Paul. Contact Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin, phone number 425-5322.

GENERAL PRACTITIONER urgently needed to join busy, well established practice in North Central Minnesota community; excellent year round recreation area, best hunting and fishing in the State. Salary negotiable for the first year, early partnership if desired. Hospital owns and maintains clinic. Call me collect. A. H. Roth, M.D., Deer River, Minnesota, office number 246-8275 or home number 246-8164.

GENERAL PRACTITIONER wanted for association leading to partnership with five Family Physicians, an Internist and a Surgeon in a modern congenial clinic environment. Rotating call schedule, ample vacation and study time. Recent deaths of two very active physicians assure an immediate practice. Community of 18,000 with excellent facilities fifty miles from Rochester and the Twin Cities. Contact: Burton A. Orr, M.D., Faribault Clinic, Faribault, Minnesota. Phone 507-334-3921.

IMMEDIATE OPENING: Internist or General Practitioner to join six man multispecialty group in northeastern Wisconsin. Excellent professional opportunity to practice in a friendly community, only two actively practicing physicians (General Practitioners) in the community outside of our clinic. Salary commensurate with training and experience first year and then full partnership. Ideal, safe small city living for the family on scenic Lake Michigan with excellent fishing, boating and hunting. All this and still only 1½ hours drive to Milwaukee or 45 minutes to Green Bay or lovely Door County. For complete details contact Robert E. Myers, M.D., Garfield at 23rd, Two Rivers, Wisconsin 54241.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

WANTED: General Practitioner or Internist, to join four man group in St. Paul. Partnership possible in one year. Dr. V. L. Sommerdorf, 1239 Payne Avenue, St. Paul, Minnesota 55101.

WANTED: Physician for opening in busy established GENERAL PRACTICE in pleasant out-state location. Salary of $35,000.00 1st year. Write MINNESOTA MEDICINE—438, 375 Jackson, St. Paul, Minn. 55101.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

WANTED GENERAL PRACTITIONER for locum tennes in February 1970 in Cook, Minnesota. Modern hospital and nursing home, well equipped clinic. Modern spacious house to live in, car furnished. Anyone wanting to take over general practice while waiting for other assignments, this would be an ideal set up. Please call 666-2261 or 666-3354, collect if interested. Wm. C. Heiam, M.D., Cook, Minnesota.

GENERAL PRACTITIONER to join two-man group, ages 35 and 38, St. Paul suburb, near lake. Excellent hospital affiliation. Estimated $30,000 plus first year, equal partner second year if mutually agreeable. Write: MINNESOTA MEDICINE—439, 375 Jackson, St. Paul, Minnesota 55101.

TEN MAN MULTISPECIALTY group needs an orthopedist, ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

PSYCHIATRIC RESIDENCIES: We offer nothing but excellent psychiatric training in a stimulating, well organized program located in a culturally advantaged community. Approved psychiatric training. Traverse City State Hospital, Michigan Department of Mental Health. Three and five year programs. Salary, 3 year program: $10,669; $11,191; $12,131. 5 year program: $12,152; $14,031; $16,328. $21,944; $23,093. NIMH-GP stipends available. Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

Cystic Fibrosis*

Current Theories Concerning the Pathogenesis*

ALEXANDER SPOCK, M.D.[†]
Durham, North Carolina

Cystic fibrosis is a generalized inherited disease of children, adolescents and young adults in which there is a dysfunction of all or most of the exocrine glands. Clinical manifestations of this disease include chronic pulmonary disease, pancreatic insufficiency, and elevated sweat electrolytes. A puzzling feature of cystic fibrosis is the marked variability in the severity of the disease in different patients, even within a single family.

The basic defect in cystic fibrosis is not known. Numerous hypotheses have been presented in an attempt to provide a unifying concept in order to explain the electrolyte and mucopolysaccharide abnormalities. These hypotheses are well summarized in several recent reviews.[1-4]

An attempt will be made to correlate this new information with the four most commonly accepted theories for the pathogenesis of cystic fibrosis. These four theories are: (1) abnormal secretions; (2) autonomic dysfunction; (3) humoral abnormality; and (4) ion transport dysfunction.

Abnormal Secretions

The abnormal secretions which occur in patients with cystic fibrosis have been recognized as the basic pathological lesion resulting in clinical symptoms due to bronchial and pancreatic obstruction. The increased viscosity of these secretions has been attributed to an *increased fucose and decreased sialic acid* levels of the glycoproteins[5] and more recently to a complex formed by the glycoprotein and calcium,[6] though there has been no delineation of the underlying biochemical defect.

Reid[7] has shown that prior to pulmonary infections, patients with cystic fibrosis have normal bronchial glands and secretions. However, with infections, hypertrophy of the bronchial glands occurs, resulting in an increased production of sulfamucins and decreased concentration or even elimination of the sialomucins.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Duke University Medical Center, Durham.

In 1968 Danes and Bearn[8] demonstrated that fibroblasts from skin biopsies of patients with cystic fibrosis stain metachromatically due to the *abnormal presence of a cytoplasmic substance*. Even more remarkably, heterozygous* relatives have similar changes in the fibroblasts. Danes[9] reports that the staining abnormalities in cystic fibrosis are of two types. In type I, the metachromasia appears diffusely throughout the cytoplasm as vacuoles; in type II, the fibroblasts show diffuse granular metachromasia. The types are genetically consistent, as in every family studied the patient and parents fall in the same class.

The metachromatic staining of fibroblasts is thought to represent acid mucopolysaccharides. Matalon and Dorfman[10] studied the acid mucopolysaccharide content of the culture fibroblasts and noted that the *total amount of polysaccharide* isolated from fibroblasts in a patient with cystic fibrosis was approximately eight to 10 times that present in normal fibroblasts. The acid mucopolysaccharide fraction contained high uronic acid, dermatan sulfate, and chondroitin sulfate 4/6 levels; however, these levels closely paralleled the distribution of these mucopolysaccharides in normal cells. Danes[9] also observed that cells of type II have an increased intracellular mucopolysaccharide content. In contrast, type I cells have no increase in intracellular mucopolysaccharide content.

Metachromatic staining has also been demonstrated in cultured white blood cells from patients with cystic fibrosis[11] and fibroblasts obtained from amniotic fluid of mothers known to have children with cystic fibrosis.[12] Since the metachromatic staining technique does not differentiate the heterozygote from the homozygote, it can not be utilized to establish the diagnosis of cystic fibrosis. Furthermore, as the metachromatic substance detected in cystic fibrosis is also seen in many mucopolysaccharides, this technique should at the present time be utilized with appropriate caution for genetic counseling.

The exact reason for the accumulation of the mucopolysaccharides within fibroblasts obtained from patients with cystic fibrosis as well as from the heterozygote is not known. Possible explanations for this occurrence include: a defect in the cell membrane, a defect in the lysozymes or a specific enzyme within the lysozyme which normally break down mucopolysaccharides, or an increased synthesis due to lack of an inhibitor.

Autonomic Dysfunction

During the past two decades numerous studies have implicated the autonomic system in the pathogenesis of cystic fibrosis.[13] The exocrine glands are innervated and controlled in their secretory activity by the autonomic nervous system, and the increased parotid secretory rate noted in patients with cystic fibrosis probably indicates *hyperactivity of the autonomic nervous system*. Eyeman et al.[14] observed an increased concentration of acetylcholine in the sweat of patients with cystic fibrosis. Chernick and Barbero[15] demonstrated that changes similar to those found in the submaxillary saliva of patients with cystic fibrosis can be induced by parasympathomimetic stimulation in normal children. In addition, the adrenergic blocking agent, guanethedine, clears the turbidity of this secretion which is characteristic of patients with cystic fibrosis. The change in turbidity was the result of a decrease in the organic constituents of the saliva; the guanethidine had little effect upon the ionic components. The action of guanethidine in reversing the turbidity associated with these secretions probably indicates that the secretory abnormality in cystic fibrosis is not of a propressively irreversible type.

Attempts to reproduce cystic fibrosis by chronic administration of pilocarpine or atropine have failed to reproduce the syndrome of cystic fibrosis. Structural and functional studies of the autonomic nervous system have failed to produce an explanation of the disease, and the various abnormalities suggestive of autonomic dysfunction in cystic fibrosis cannot be adequately correlated with each other. Barbero[16] postulates that it is unlikely that a generalized disturbance of the autonomic nervous system occurs in cystic fibrosis. It is more likely that the site of the defect is at the neuroglandular junction or within the secretory end organ itself.

---

*See Test Your Word Score Page 1401.

Humoral Abnormality

The possibility that cystic fibrosis has as its basic defect the production of either *abnormal hormone or increased concentration* of a normally occurring hormone capable of stimulating exocrine tissue has been studied only recently. The evidence for this theory is based primarily on the results of Spock et al.,[17] who demonstrated a serum factor in patients with cystic fibrosis and in parents of children with cystic fibrosis.

Utilizing a bio-assay method, Spock et al.[17] observed that serum from patients with cystic fibrosis disorganized the ciliary rhythm in explants of respiratory epithelium. This effect was absent from the serum of patients having a variety of diseases with clinical features similar to those seen in cystic fibrosis. The serum factor was also detected in the parents of children with cystic fibrosis; however, the concentration of the factor was lower. The serum factor was heat-labile, nondialysable and, upon chromatographic examination, appeared with the macroglobulin fraction as well as between the gamma globulin and albumin peaks. The mechanism by which the serum factor produces disorganization of the ciliary beat is not yet understood. However, these authors postulated that the macromolecules in the serum may alter transport of electrolytes across the cell membrane, thereby producing change in the action potential within the cell with subsequent disorganization of the ciliary beat. This study also noted that the ciliary activity of explants from patients with cystic fibrosis was normal when not exposed to the patient's serum.

Verification of the above mentioned results has been made by Bowman et al.[18] who noted that serum from patients with cystic fibrosis and heterozygotes produced cessation of ciliary activity of oyster gills within 35 minutes. In contrast, sera from only two of 64 individuals without cystic fibrosis inhibited ciliary activity within this time. This serum factor shares properties in common with the serum factor noted by Spock et al.[17]

The humoral theory for cystic fibrosis does not explain such observations as the presence of the disease in the fetus, occurrence of a generalized and varied disease due to a single hormone, and restriction of humoral influence only to exocrine function.

Ion Transport Dysfunction

The sweat electrolyte abnormality consisting of *elevated sodium and chloride* levels is present in virtually all patients with cystic fibrosis. Using micropuncture techniques, Schulz[19] has demonstrated that this abnormality is the result of a defect in the reabsorption of sodium chloride by the duct of the sweat gland. The sweat gland does not show any anatomical or enzymatic defects in the glands of patients with cystic fibrosis to account for dysfunction of the gland.

In 1967 Mangos and McSherry[20] noted that when saliva or sweat from patients with cystic fibrosis was introduced by retrograde injection into the parotid glands of rats, marked inhibition of sodium reabsorption occurred; but retrograde perfusion with normal saliva or sweat from normal children did not affect the rate of sodium reabsorption. The effect was also shown not to be due to inhibition of the ATPase enzyme. Subsequent studies by Mangos[21] have shown that inhibition of sodium reabsorption was also produced by retrograde injection into the parotid glands of rats of positively charged substances, e.g., protamine sulfate, poly-L-lysine. In contrast, when the saliva of patients with cystic fibrosis was mixed with a negatively charged substance (heparin or polyglutanic acid) and injected in the same manner, the sodium transport inhibitory effect of the saliva practically disappeared.

Mangos[22] has studied the effect of euglobulin from patients with cystic fibrosis upon the rat parotid gland system. The euglobulin did not cause any inhibition of sodium reabsorption; however, fractionation of the euglobulin disclosed a small polypeptide capable of producing marked inhibition of sodium reabsorption. This fraction of serum was also capable of producing disorganization of the ciliary beat in the bio-assay system. Mangos, McSherry, Benke and Spock[23] have also demonstrated that rats treated with 5 mg of isoproterenol SO_4 for three weeks developed marked enlargement of the salivary glands, quantitative and qualitative changes in the excretion of basic macromolecules in parotid saliva, increased sodium concentrations in the parotid saliva, and appearance of a factor in the serum of these rats resulting in ciliary dyskinesis.

A red-cell transport defect in patients with cystic fibrosis and their parents was recently reported by Balfe, Cole and Welt.[24] This investigation demonstrated a diminished active transport of sodium in the erythrocytes of patients with cystic fibrosis. Of special significance is the marked decrease in pump II in the parents. Previous studies[25] noted the sodium pump in erythrocytes to be functioning normally.

The theory of ion-membrane dysfunction in cystic fibrosis may unravel the confusion concerning the basic defect seen in this disease; however, as of today our knowledge concerning cellular membrane structure and transport is too limited to provide such a solution.

Summary

The diverse and at times conflicting statements concerning the pathogenesis of cystic fibrosis presented in this paper reaffirm our inability to identify the basic defect in cystic fibrosis. However, with currently available evidence the following hypothesis can be proposed. A humoral substance present in the body fluids of patients with cystic fibrosis attaches to or acts upon the membrane surface of cells of the exocrine gland. The interaction of the humoral substance with the cell results in increased metabolic activity within the cell with subsequent alteration of cell membrane permeability and increased protein and mucopolysaccharide synthesis.

Cystic Fibrosis*

Pathogenesis of the Pulmonary Lesion

GORDON E. GIBBS, M.D.†
Omaha, Nebraska

THE PULMONARY COMPLICATIONS in cystic fibrosis are considered to be on an obstructive basis due to viscid materials in the airways, with dilatation and infection occurring in the airways which are occluded. The chronic obstruction increases susceptibility to infections, and metaplasia of bronchial and tracheal epithelium occurs.

In the earliest lesions, Hemophilus influenzae, Klebsiella pneumoniae and Staphylococcus aureus are often found. As the lesion progresses, Staphylococcus aureus is more consistently present. Pseudomonas aeruginosa eventually appears and may become the only pathogen.

Marked variability of the manifestation of cystic fibrosis occurs in the lungs and in many other organs: the pancreas, liver, salivary glands. The glandular organs show a ductular obstructive process. Engorgement occurs in the salivary, bronchial, duodenal and rectal mucous glands, suggesting the pathogenic role of mucus abnormality. The excess salinity of the sweat, however, suggests that the defect is also in the secretory process and not limited to the mucous glands.

Later stages of development of the pulmonary lesion involve bronchiectasis, bronchitis shading into pneumonia, atelectasis followed by pneumonia or abcess, emphysema, pulmonary fibrosis, and at times cavitation and hemorrhage. The vital capacity gradually diminishes, but an excessive proportion of residual volume occurs. The terminal event is usually anoxic failure, with a heart burdened by excessive pulmonary artery pressure. Anoxia is finally precipitated by accumulation of mucopurulent material in the respiratory tract. This is accelerated pre-terminally with failure of effective coughing and carbon-dioxide narcosis. This sequence of events is a classical concept in cystic fibrosis.

†Department of Pediatrics, University of Nebraska College of Medicine, Omaha.

In order to get a look at an early pulmonary lesion, a 1948 case was recalled. A boy died at the age of eight years due to hemorrhage from esophageal varices. Death was complicated by hepatic failure and cerebral edema. He had complete pancreatic deficiency and hepatic cirrhosis with little or no clinical evidence of pulmonary involvement, although pulmonary function tests had not been done.

This original protocol stated that there was slight but definite evidence of pulmonary involvement, mainly bronchiolar. Grossly, the bronchi were free of secretion. Histologically, the tracheal epithelium was intact, but the submucosa was infiltrated with a moderate number of plasma cells. The bronchi showed intact columnar epithelium; smaller bronchi were partially filled with exudate which contained some mucoprotein, as indicated by a PAS stain (Figure 1), and there was slight inflammatory reaction around these small bronchi. Bronchioles showed more filling with mucopurulent secretion and more inflammatory reaction in the surrounding area (Figure 2). There were some areas of thickened alveolar walls with inflammatory reaction, (interstitial pneumonitis) and some disruption of alveolar walls as emphysema.

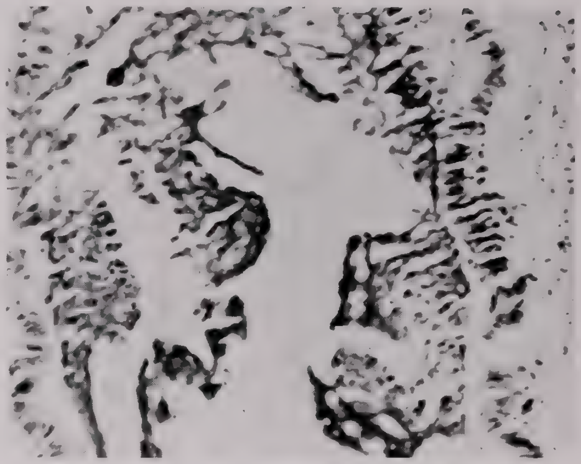

Fig. 1—Small bronchial branch showing relatively acellular exudate with mucoprotein stained by PAS.

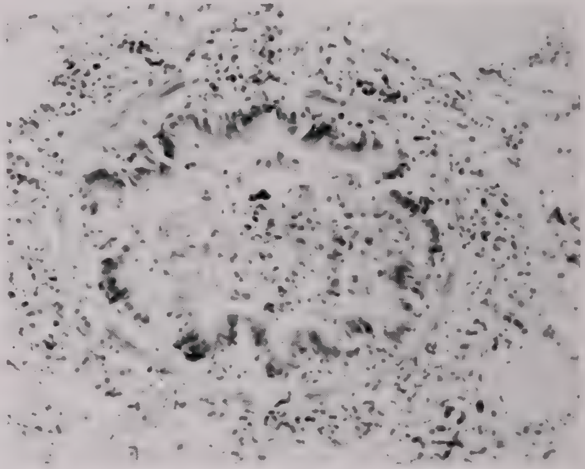

Fig. 2—Bronchiole filled with mucopurulent exudate and surrounded by inflammatory reaction. The epithelium is intact. H & E.

Summary

The first step in the muco-obstruction of the bronchial tree in cystic fibrosis is in the bronchiole. This tends to peripheral bronchiolar infections and peripheral air trapping and explains the tendency toward emphysema and atelectasis observed in infants with cystic fibrosis.

Acknowledgment: This study was supported in part, by the National Cystic Fibrosis Research Foundation.

The Mining-Camp Medic

A mining-camp doctor was accustomed to long hours and long miles. A Sacramento physician started Sunday, June 21, 1868, at 4 A.M. Before he went to bed that night between 10 and 11 P.M., he had worn out three horses to make a total of 100 visits to 87 different families. Only the toughest horses could stand a dedicated doctor's pace. To get such a horse Dr. Gardiner tamed a wild bronco with whiskey and mash until it was so docile it followed him about as if it were a dog. When a drunk threatened to shoot his horse one day, the doc pulled a gun on him.*

Chronic Lung Disease*

Clinical Evaluation of the Child

WILLIAM W. WARING, M.D.
JUDITH A. HARRIS, M.D.
New Orleans, Louisiana

PULMONARY FUNCTION TESTING begins with a clinical quantitative approach to the child during the physical examination. No laboratory is required for its performance or interpretation. It lends itself easily to serial use in the same patient; in fact, it is of greatest value when routinely employed on each clinic visit. It is painless and calls for no effort from the child. It is independent of the variability produced by an examiner's bias because it is objective. Since only minimal cooperation is required, it is applicable throughout all or most of childhood. Finally, it is an index of certain aspects of pulmonary disease that may be impossible to measure directly, such as obstruction, restriction, and destruction.

In spite of these advantages, the application of an emphatically quantitative physical examination calls for a mind that enjoys precision and delights in maintaining careful charts in a patient's record. Other minds will prefer more traditional qualitative methods. Perhaps even more, quantitation appeals to physicians who treat children with chronic lung disease, such as asthma or cystic fibrosis, because it gives them additional objective evidence of the course of each child's disease. Thus, these measures probably have diagnostic, therapeutic, and prognostic values.

Chronic Cough

One significant criterion for chronic pulmonary disease could be whether a child coughs at some time every day for three months. He then has, by definition, chronic pulmonary disease. Cough was selected because it is a very common sign or symptom of lung disease. Admittedly, there may be disease without cough, but cough is a very good way of locating a large group of patients with prolonged pulmonary disease. If an individual coughs even once, it is a sign of abnormality, since a cough is always a reaction to some insulting effect. In the evaluation of any child with cough, three quantitative approaches concern us: respiratory rate, thoracic depth and width, and two diameters of the left index finger. Tachypnea* will be considered an index of restriction; thoracic deformity an index of obstruction, and finger clubbing an index of destruction within the lungs. Let us see if dividing children who cough into these subcategories will allow more complete evaluation, both diagnostically and prognostically.

Public Health Service, National Institute of Arthritis and Metabolic Disease (No. 1 RO1 AM12752-01), and by a contract from the Chronic Respiratory Diseases Control Program of the Public Health Service, Department of Health, Education and Welfare (No. CCD-69-50). Views expressed by the authors are not necessarily those of the Public Health Service.

General Types of Pulmonary Disease

Restrictive Lung Disease

One of the oldest tests of pulmonary function is a well counted *respiratory rate*. We cannot take a crying, restless, or even anxious child, and use a rate counted on him for this type of test. Ideally, we need a tranquil child, perhaps sitting or sleeping in his mother's lap. Also, because of slight variations in the rhythmicity of the respiratory rate, we have to count for one, two or three minutes, taking the average count per minute.

One of the characteristic physical findings in restrictive lung disease is fast, shallow respirations: tachypnea and hypopnea. Stiff lungs require greater than normal work by the muscles of respiration; this work can be minimized by shifting from a normal breathing pattern to a faster and shallower one.

It follows that the respiratory rate becomes an index of restrictive lung disease. Other causes of tachypnea must be ruled out or otherwise interpreted: age, fever, anemia, thyroid disease, exercise, anxiety, and shock. The faster the rate, the stiffer the lungs; the stiffer the lungs, the greater the restrictive disease.

The term "restrictive" implies space-occupation: lobar pneumonia fills alveoli, so that they can no longer share in the gas-exchange function of the lungs; a large pleural effusion or pneumothorax compresses and "restricts" the lung from the outside; neuromuscular disease or lobectomy "restricts" lung function by limiting ability to ventilate. The diagnosis of restrictive disease depends on history, physical examination, and radiography; it is confirmed by pulmonary function testing which usually indicates a decreased vital capacity and frequently a stiffer, less compliant lung, one that requires a greater pressure change acting on it to produce a given change of volume.

Obstructive Lung Disease

Obstructive lung disease, an almost self-explanatory term, is the sum of effects resulting from the fact that the airway at one or more points lacks normal diameters and that therefore the to-and-fro movement of tidal volume is variably impeded. The causes of obstruction may be intraluminal (mucus, pus, foreign body), mural (bronchospasm, edema, inflammation), or extrabronchial (vascular or nodal compression). Regardless of its cause, obstruction makes necessary greater than normal inspiratory and expiratory pressures in order to maintain ventilation. Asthma, bronchiolitis, and cystic fibrosis produce prominent and more or less diffuse obstruction, affecting many bronchi and bronchioles.

Physical findings of obstruction include wheezing, various types of cough, prolongation of expiration, and retractions or bulging of intercostal spaces.

It has long been recognized that chronic obstructive lung disease of certain types (obstructive emphysema in adults, asthma and cystic fibrosis at all ages) is associated with a characteristic thoracic deformity, called "barrel chest," in which thoracic anteroposterior diameter is markedly increased. This effect is best explained as an application of Pascal's principle,[1] which predicts that a malleable nonspherical gas or fluid-filled object will approach a sphere as pressure within it is increased. (A simple example of Pascal's principle is the progressive obliteration of the ears and nose of a "Mickey Mouse" balloon by progressive inflation. With increasing pressure such a balloon ultimately assumes a perfect sphere, if it does not burst.) It follows that any lung disease that increases expiratory intrathoracic pressure will deform the chest and that the more severe the obstruction and the longer its duration, the greater will be the deformity and the more spherical the thorax. Accurate measurement of thoracic diameters facilitates early recognition of deformity and documents trends resulting from natural variations in disease severity or the effects of therapy.

---

*See Test Your Word Score Page 1401.

Destructive Lung Disease

"Destructive" lung disease is more of a pathological concept than a physiological one. The classical example of destructive lung disease in childhood is bronchiectasis, whether it be secondary to the atelectasis produced by a foreign body or to that produced by mucous plugging in cystic fibrosis. In either case, the destructive process begins with bronchial obstruction and is followed by atelectasis and pyogenic infection. The end results are saccular bronchial dilatation, bronchorrhea with productive cough, diminished ventilation, and varying degrees of digital clubbing. Other types of destructive lung disease, such as obstructive emphysema and reinfection tuberculosis, do not occur to any significant degree during childhood.

Clubbing may be used as a general measure of destructive lung disease, provided one rules out non-pulmonary and non-destructive pulmonary diseases associated with it. Although it occurs in benign idiopathic instances, occasionally hereditary, such examples are rare. It is consistently seen in congenital cyanotic heart disease and in congenital pulmonary arteriovenous anastomoses. It may occur in biliary cirrhosis, chronic ulcerative colitis, and subacute bacterial endocarditis.

No case is made here for the *specificity* of clubbing as a parameter of destructive lung disease. Furthermore, once the association has been made with a disease, such as cystic fibrosis, something about the extent and the severity of the lung disease in that patient may be related to the degree of clubbing in a way not completely understood. In any event, a method of quantitating clubbing is useful in following children with "destructive" lung disease such as cystic fibrosis. Its appearance in an "asthmatic" child should arouse suspicion of the accuracy of the diagnosis, since it rarely appears in uncomplicated asthmatic patients, regardless of the severity or chronicity of their disease.

Limits of Normality

Serial Measurements

One of the inevitable problems with objective measurements is not so much what the expected or average value is for an individual but rather how much variability or "scatter" may exist about the expected value and still be considered "normal." Most measurements in childhood normally vary with sex, age, height, or weight, which are then often called independent variables. All pediatricians are familiar with boys' and girls' charts for height and weight, which are usually plotted as a function of the independent variable, age. Limits of normality are calculated either in percentile or standard deviation units. Regardless of the choice, it is clear that the farther an observed value falls from the expected mean value, the greater its chance of being abnormal.

The above holds for a single observation, such as the first time weight is recorded on a patient. With serial measurements on the same normal individual, one soon learns that the intra-individual variability is considerably less than that of the whole normal population. Each subject "seeks his own level" in the normal population. Changes of a few percentile points or one standard deviation may then be very significant. Hence one sees the value of frequently repeated determinations on the same patient.

The Growth Factor

The problem here is how to separate the effects of growth from those of disease. For most pulmonary function tests in children it has been found that height is usually the most satisfactory independent variable (the one minimizing the variability or scatter of dependent variable values). A graph, which becomes a permanent part of the patient's clinical record, is of great value since it shows clearly and quickly the trends of serial measurements.

Respiratory Rate

It may seem no innovation to suggest that an accurate respiratory rate is part of a good physical examination.

Sleeping Rate

To count the rate of an anxious or crying child with a stethoscope is a waste of time. It may be that on a given clinical visit the physician will not have the opportunity to get an accurate count; if so, it is better to take none than to introduce inaccurate data into the record. The place of the parent as an observer should be recognized. A parent can be taught how to observe and record sleeping respiratory rates. Such counts, taken at the parents' bedtime, may afford invaluable data on the course of pulmonary disease (Figure 1).

Normal Limits

The data of Iliff and Lee[2] for respiratory rates are for quiet or sleeping children. The rates are expressed in means and standard deviations for both sexes with age as the independent variable (Table). For example, "normal limits" (x ± 2 SD) for respiratory rate for a 4½-year-old boy would be 23 ± 4, or from a rate of 19 to one of 27 per minute.

The early recognition of the respiratory distress syndrome in the newborn which causes increasing stiffness of the lungs, is manifest by an increased rate.[3] Recovery is thus associated with loss of stiffness and a return of the respiratory rate to normal.

Less variability (smaller standard deviations) might be observed if only sleeping respiratory rates were counted and if such rates were plotted as a function of stature, rather than age. The studies mentioned above should be extended in order to obtain information on the best independent variable (height, weight, or age), and to define values during the first year of life when the respiratory rate is dropping most rapidly from the normal newborn mean of about 47 per minute.

Barrel Chest

Pectus profundum implies a deforming of the thorax from its normal elliptical cross-sectional shape to a more circular one. The problems here in assessing thoracic deformity stem from physiological changes in both chest shape and size during the growth process. A newborn has an almost circular chest and, as the child grows, both thoracic transverse diameter (width) and anteroposterior diameter (depth) increase, but depth increases less than width and, as a result, the chest gradually assumes the more elliptical shape of the normal adult.

Thoracic Index

It is possible to measure chest depth and width with obstetrical calipers. Division of depth by width yields the thoracic index

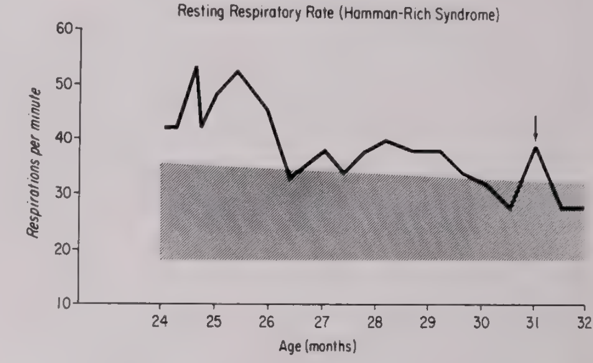

Fig. 1— Respiratory rate in a child with Hamman-Rich disease proven by open lung biopsy. Shaded area indicates normal range of respiratory rate for age. Counts were taken on serial visits to the clinic. Arrow indicates an acute respiratory infection. Corticosteroid dosage in this child was largely controlled by monitoring the respiratory rate. (Reproduced by permission of the editors, *The Bulletin of the Tulane University Medical Faculty, 27*:221, 1968.)

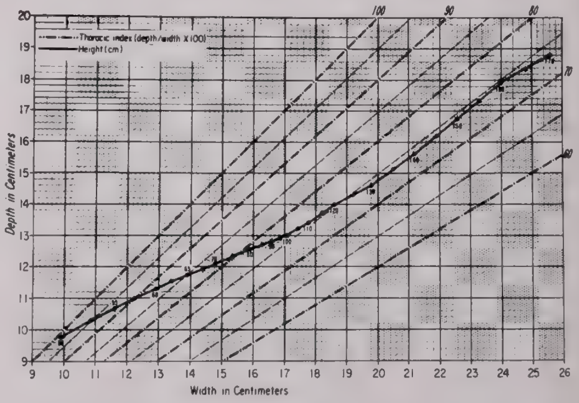

Fig. 2—Photograph of a page of the chest graphing system in use in the pediatric chest and cystic fibrosis clinics. See text. (Reproduced by permission of the editors, *The Bulletin of the Tulane University Medical Faculty*, 27:221, 1968.)

(depth-width ratio). As the thoracic index approaches unity, the chest approaches a perfect circle in cross section.

A graphing system has been developed that allows one to plot chest depth as a function of chest width and to read directly the thoracic index without the need of any further computation*. The graph also permits a physician to decide in standard deviation units how much depth, width, and thoracic index differ from expected values for children of the same sex and height (Figure 2).

As always, serial determinations are of infinitely greater value than single ones, since trends produced by the disease or by a treatment program can be assessed. Increasing deformity is a poor prognostic sign in cystic fibrosis; it also argues for a more vigorous treatment program in asthma.

Significance of Deformity

Although the necessary correlations have not as yet been made, it is a reasonable hypothesis that increasing deformity correlates with increasing functional residual capacity, that is, with the volume of air remaining in the lungs at the end of a quiet expiration. It is thus a measure of air trapping produced by chronic obstructive pulmonary disease.

With this graphing system it has been shown that children with cystic fibrosis have significantly deformed chests, primarily as a result of increases in their anteroposterior thoracic diameters. Children who subsequently die with chronic obstructive disease associated with cystic fibrosis have more severe deformities than those who continue to live, confirming the prognostic value of such measurements.

Digital Clubbing

Although clubbing of the digits has been associated with pulmonary disease since Hippocrates, its cause is still unknown. Provided congenital cyanotic heart disease can be ruled out, most digital clubbing in childhood can be related to bronchiectasis, itself a destructive process in the lung.

A method has been developed of making and measuring casts of the left index finger; the method is simple and can be learned by an office nurse for routine use. A permanent

TABLE

Normal Resting Respiratory Rate per Minute

Age (Years)	Boys Mean ± SD	Girls Mean ± SD
0- 1	31 ± 8	30 ± 6
1- 2	26 ± 4	27 ± 4
2- 3	25 ± 4	25 ± 3
3- 4	24 ± 3	24 ± 3

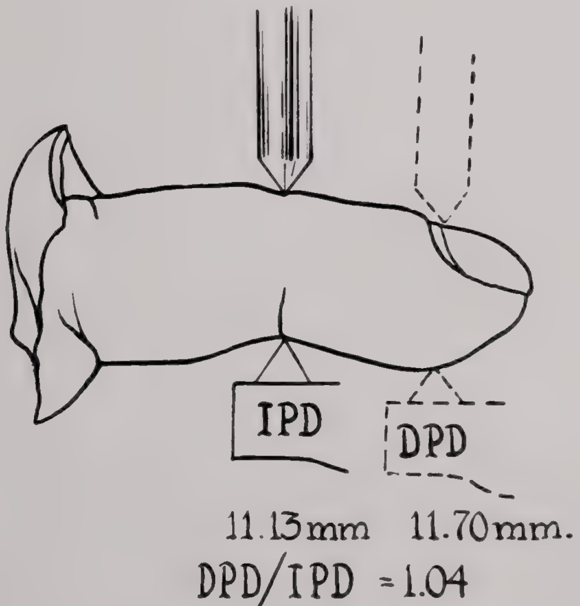

Fig. 3—Method of measuring casts of the index finger with a micrometer. Depicted cast demonstrates definite early clubbing. (Reproduced by permission of the editors, *The Bulletin of the Tulane University Medical Faculty*, 27:221, 1968).

---

*These graphs have been printed by Mead Johnson Laboratories and are available without charge from the company. Each graph contains instructions for obtaining, plotting, and evaluating the two measured diameters.

record is thus obtained of the exact size and shape of the distal two phalanges of the index finger, complete even to the dermatoglyphic lines. A micrometer is used to measure the depth of the cast at the base of the nail (the distal phalangeal depth) and another depth at the distal interphalangeal fold (Figure 3). Distal phalangeal depth divided by interphalangeal depth then becomes a measure of the deformity of the terminal phalanx of the finger associated with clubbing. This ratio differentiates, better than other measurements, the fingers of children with diseases associated with clubbing from those of normal children. The ratio of the distal phalangeal depth to the interphalangeal depth is normally independent of sex, age, height, and weight from infancy into adulthood. Since the normal ratio is 0.895 with a standard deviation of .041, a value of 1.0 (equivalent to about 2½ standard deviations above the mean) has been adopted as the cut-off point between normal and abnormal values.

The practical value of these observations lies in the fact that a decision of whether a patient has clubbing or not can be made during the physical examination by a careful inspection of the lateral aspect of the *index* finger. The finger is clubbed if the depth of the finger at the base of the nail exceeds that at the terminal interphalangeal fold.

By the cast measurement system, clubbing can be quantitated and its changes with time and treatment evaluated. Serial observations of the ratio of the distal phalangeal depth to

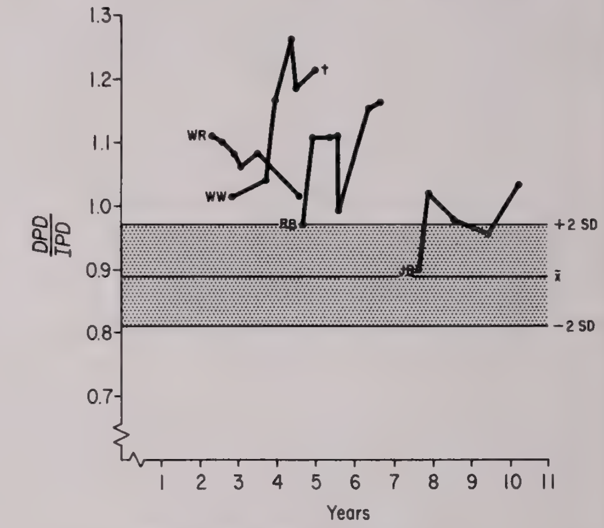

Fig. 4—Serial measurements of the ratio of the distal phalangeal depth to the distal interphalangeal fold ratio of finger casts of four boys with cystic fibrosis. Note the fluctuation in clubbing and the prognostic implications in WW whose clubbing became progressively more severe until his death (†).

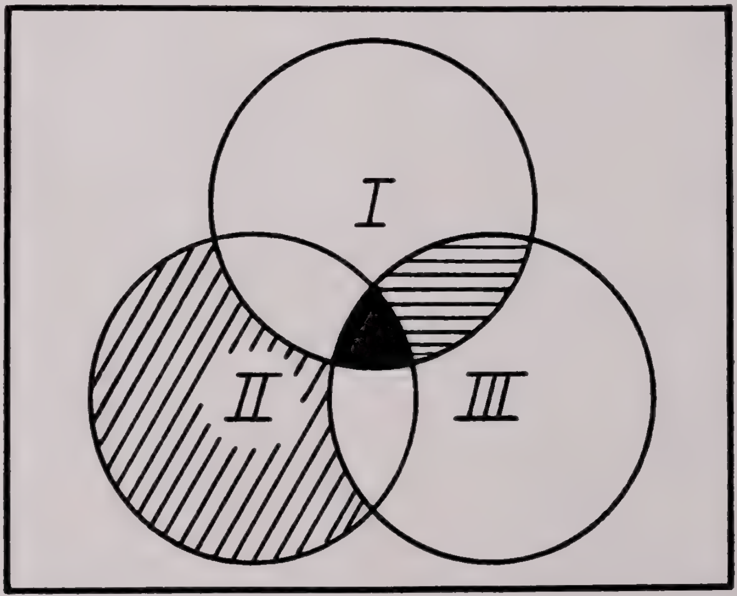

Fig. 5—A Venn diagram, showing all possible combinations of tachypnea (Set I), chest deformity (Set II), and clubbing (Set III) that can occur in a group of children with chronic pulmonary disease. (Reproduced by permission of the editors, *The Bulletin of the Tulane University Medical Faculty,* 27:221, 1968.)

the distal interphalangeal depth in children with cystic fibrosis (Figure 4), some of whom have had a dozen or more casts made over a period of several years, show curious but real increase in the severity of their clubbing.

Discussion

Since varying combinations of restriction, obstruction, and destruction occur in different types of chronic pulmonary disease, it may be possible to make a fairly accurate diagnostic guess of the basic disease by evaluating these three clinical measures. The use of a Venn diagram may clarify this point (Figure 5). In this diagram the outer rectangle encloses a group of children with chronic lung disease of at least three months' duration, as defined by obvious clinical symptoms, such as cough. All of these children will be seen by a physician because of the severity or chronicity of their disease manifestations. On physical examination a certain number will have significantly elevated respiratory rates. This "set" is separated from the children without tachypnea by placing them in a circle (Set I) within the rectangle.

It is also possible to define by significant chest deformity and significant clubbing two other groups (Sets II and III, respectively), which also are indicated by circles within the rectangle. Various combinations can be depicted by having the circles intersect. Thus, children in the center of the diagram, where all circles intersect, have tachypnea, chest deformity, and clubbing; those enclosed by the intersection of circles I and II have tachypnea and chest deformity, but do not have clubbing, and so on. Thus the Venn diagram shows all possible combinations of the three quantitated factors, including a group (outside the circles) with none of the factors but who still have chronic cough.

Experience suggests that the group of children with tachypnea, chest deformity, and clubbing (solid area, Figure 5) usually have cystic fibrosis; those with chest deformity alone have asthma (diagonal lines); and those with clubbing and tachypnea (horizontal lines) have bronchiectasis due to agammaglobulinemia or foreign body. Whether such a potential diagnostic value of the quantitative physical examination will stand rigorous prospective application remains to be tested. Pending such a test, however, one can still say that the prognostic and therapeutic implications of quantitation of clubbing and chest deformity have been reasonably established and are sufficient to justify their continued use.

Finally, this approach has great teaching value, since it helps relate pulmonary physiology, pathology, biostatistics, physical diagnosis, and therapeutics as they apply to the effects of chronic lung disease in any patient.

Summary

The "quantitative" physical examination of the lungs begins with precise measurements of (1) the resting or sleeping respiratory rate, (2) the chest depth and width, and (3) the index finger depth at the base of the nail and at the terminal interphalangeal joint.

These measurements are related to a distribution of the same measurements in normal individuals and are expressed in relation to such normal distributions (standard deviations above or below normal mean).

Tachypnea is taken as an index of restrictive lung disease, chest deformity of obstructive lung disease, and digital clubbing of "destructive" lung disease (bronchiectasis).

Such quantitation has both therapeutic and prognostic values in children with cystic fibrosis.

A Venn diagram can be used to portray logically the potential diagnostic value of this approach.

Acknowledgment

The authors are grateful to Marilyn McConnell, R.N., who routinely measures the chests and casts the index fingers of children attending the Tulane Pediatric Chest Clinic and New Orleans Cystic Fibrosis Clinic. They also thank Pamela Buchanan, B.A., who measured DPD and IPD of the finger casts.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

EDUCATION PLUS: What midwestern high school of 170 boys currently has alumni at Harvard, Princeton, Swarthmore, M.I.T., McGill, London and Oxford (Rhodes Scholar), welcomes Americans, and produces great hockey teams? St. Johns-Ravenscourt School, Winnipeg 19, Manitoba. Headmaster: H. John P. Schaffter, M.A. (Cambridge), 204-453-3016.

THE ADOLF GUNDERSEN MEDICAL FOUNDATION of La Crosse, Wisconsin, announces the establishment of a fully accredited three-year residency training program in Internal Medicine at Lutheran Hospital, La Crosse, Wisconsin. The hospital staff consists of a 65-man multiple specialty group with offices in a connecting modern clinic building. Eighteen fully qualified internists serve as a nucleus of the teaching program. All staff men are full-time and salaried. This clinic-hospital complex serves as a referral center for a 100-mile radius. The hospital has a 375-bed facility. An intensive in-house training program is supported by weekly guest consultants. Stipend: $600 to $700 per month, plus housing and miscellaneous. Located in a progressive community with expanding university and private college. Population 50,000. Excellent school and recreation facilities. Applications being considered at all levels. Write: Edwin L. Overholt, M.D., Director, Medical Education and Research, Gundersen Clinic, Ltd., 1836 South Avenue, La Crosse, Wisconsin 54601.

Success

To all who labor in the shadows cast by older brothers and sisters, we offer the following consolation: Elias Howe, of sewing-machine fame, was the eighth child in his family; Inventor George Westinghouse was the ninth; Novelist James Fenimore Cooper was the eleventh; Charlie Gehringer, the Detroit baseball star, was the twelfth; Naturalist Luther Burbank was the thirteenth; and the versatile Benjamin Franklin was the fifteenth.*

---

*This Week

One of these disposables comes prefilled.
Its unit dose – in nonreactive glass
cartridge – is premeasured.
The cartridge is clearly labeled:
drug name, strength, control number.
Even expiration date where appropriate.

You're more confident that the patient gets…

...just what the doctor ordered with the Tubex Closed Injection System.

Injections with the Tubex system are as easy as 1, 2, 3,

1. Select—from an extensive variety of prefilled Tube sterile cartridge-needle units.* No multi-dose vials to bother with; no unlabeled syringes to cause confusion

2. Inject—with a minimum of pain. Thanks to the single-use, stainless-steel needle that's both ultra-sharpened and siliconized. Aspirate simply and conveniently.

3. Throw away—empty cartridge-needle unit. Never used again, it can't transmit infection. And there's no clean-up job.

*For injectables not yet in the ever-expanding prefilled Tubex line, empty sterile cartridge-needle units are available.

The Pulmonary Function Laboratory[*]

Role in the Evaluation of Pulmonary Disease in Children

V. CHERNICK, M.D.[†]
Winnipeg, Manitoba

There can be no argument about the diagnostic value of emergency testing of pulmonary function, that is, the estimation of arterial blood gases and pH in such conditions as coma of unknown cause, cyanosis, respiratory insufficiency or acid-base disturbances. However, the pulmonary function laboratory has another role in the elective testing of children with pulmonary function disease, which is not immediately essential for the management of those particular patients.

Reasons for Assessing Pulmonary Function

Pulmonary function evaluation as an aid in differential diagnosis is most useful in the adult patient specifically in an attempt to distinguish between chronic bronchitis, emphysema and asthma. It is of little help in aiding diagnosis in children with chronic chest disease. Pulmonary function tests prior to surgery in elderly adults may be useful in predicting possible complications and help in the postoperative management. The assessment of disability such as dyspnea, impaired ability to work, etc. is useful mainly in adults and particularly for compensation cases.

In the pediatric age group the pulmonary function laboratory has its greatest usefulness in its ability to apply objective methodology to the quantitation of the degree of abnormality and in allowing the objective testing of the results of our therapy. The use of sophisticated techniques has led to a greater understanding of the pathophysiology of pulmonary diseases in infants and children.

Pathophysiology of Pulmonary Disease

In a functional classification of pulmonary diseases it is possible to define two major groups: The so-called restrictive group caused by diseases of the lung parenchyma and those affecting the chest wall, and the obstructive group which may affect upper or lower airways.

---

[*] Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

[†] Associate Professor of Pediatrics and Physiology, University of Manitoba. Director, Respiratory Service, Children's Hospital, Winnipeg, Manitoba.

All diseases of the chest can be fitted into this functional classification on the basis of their principal functional abnormality. However, some diseases, for example cystic fibrosis, may have features of both an obstructive airway disease and a parenchymal disease, particularly when lung tissue is destroyed.

All of these diseases appear to result in similar physiologic abnormalities, that is, they lead to a mis-matching of ventilation and perfusion in the lung, which is one of the commonest causes of hypoxemia. There is an increase in the work of breathing which increases both the metabolic demand for oxygen and the amount of CO_2 produced which subsequently must be eliminated by the lungs. When severe, a particular process may lead to a decrease in alveolar ventilation with consequent CO_2 retention, respiratory acidosis and hypoxemia.

There are conditions outside of the chest cage which may adversely affect alveolar ventilation and produce abnormalities of the blood gases, for example, barbiturate intoxication or anesthesia. The resultant effect of these abnormalities of pulmonary function is hypercapnia, hypoxemia and acidemia. The acidemia may be both a respiratory and a metabolic acidosis. In order to functionally classify a particular disease that a patient presents with, a history, physical examination and radiologic examination are extremely important. In addition, it is possible by using simple pulmonary function tests to delineate between restrictive and obstructive disease and to quantitate the degree of abnormality.

Restrictive Disease

Disease of the lung parenchyma may be associated with a decrease in lung volume, as in pneumonia, atelectasis or bronchiectasis, or by a decreased distensibility of the lung, such as in hyaline membrane disease or pulmonary fibrosis. Examples of diseases which may affect the chest wall are kyphoscoliosis, phrenic nerve palsy and polio.

By simple spirometry one can measure the vital capacity (the sum of the respiratory reserve volume and the expiratory reserve volume); in restrictive disease it is found to be reduced. For example, following a lobectomy where 25 per cent of the lung has been removed, all lung volumes, including residual volume or the functional residual capacity, appear to be reduced and are reduced to the same extent. There is no impairment in the ability to forcibly expire most of the vital capacity within one second following a maximal inspiration.

Obstructive Disease

Obstructive diseases of the airways may affect upper airways, such as in choanal atresia* or foreign body aspiration, or lower airways, such as in asthma.

In contrast, the patient with obstructive disease such as asthma has a reduced vital capacity primarily on the basis of an increase in the functional residual capacity. There is a marked reduction in the volume of air which can be forcibly expired after one second following a maximal inspiration because of obstruction to air flow. The measurement of vital capacity and timed vital capacity, that is, the percentage of the vital capacity that can be forcibly expired in one second, is one of the simplest and most informative tests that can be done. It does not take expensive or sophisticated equipment and can be accomplished in a few minutes. However, with the use of more complicated measurements it has been possible to achieve a greater understanding of the pathophysiology of a number of disease processes.

Asthma

Asthma is associated with an increase in the allergic reactivity of the bronchial smooth muscle, and there may or may not be a superimposed respiratory infection during the acute attack. The allergic hyperreactivity results in bronchospasm, edema of the bronchiolar epithelium and accumulation of viscid mucus, resulting in expiratory airway obstruction, ventilation-perfusion abnormalities and, in severe cases, areas of atelectasis because of mucous plugs. The expiratory airway obstruction leads to a marked increase in the work of breathing; the patient has an increased functional residual capacity and residual volume accounting for the increase in the anteroposterior diameter of the chest. Obstruction of airways is associated with an increased frequency of pneumothorax in such patients. The increased work of breathing, when marked, leads to alveolar hypoventilation with resultant hypercapnia and hypoxemia. Hypoxemia is also caused by the ventilation-perfusion abnormalities and because of blood flow through areas of lung which are not ventilated. An insufficient supply of oxygen for aerobic metabolism is associated with a pyruvic and lactic acidemia and hence a metabolic acidosis.

---

*See Test Your Word Score page 1401.

The respiratory acidosis is associated with clinical symptoms of restlessness, fatigue, and anxiety, and when very severe leads to delirium and stupor. The end result in very severe cases of asthma is shock and cardiac arrest. With this pathogenetic scheme in mind, therefore, we can direct our therapeutic approach to decreasing bronchospasm, decreasing the viscosity of mucus, providing oxygen and treating respiratory failure when it supervenes.

Cystic Fibrosis

Evaluation of the mechanical properties of the chest in a patient with moderately-severe cystic fibrosis reveals an increase in the rate of respiration and in the minute ventilation. A large proportion of this minute ventilation is wasted or dead-space ventilation so that, despite the increased work of breathing, a great deal of the effort is wasted. The vital capacity is decreased as is the one-second vital capacity, denoting airway obstruction. The compliance of the lungs is decreased so that it is more difficult to move air in and out; the vital capacity is decreased because of an increase in the residual volume, and this can be noted clinically in the expanded anteroposterior diameter of the chest wall. Direct measurements of airway resistance confirm the increase of resistance.

How well are blood and gas matched within the lung? Washing nitrogen out of the lung by breathing 100 per cent oxygen is inefficient in these patients, showing that there is maldistribution of ventilation, that is, large portions of the lung which are very poorly ventilated. I have already mentioned that the dead-space ventilation is increased. These patients have large arterial-alveolar nitrogen gradients, a test which is used to denote how well alveoli are matched in terms of ventilation and perfusion. An increase in the a-A nitrogen gradient demonstrates poor matching of blood and gas primarily caused by alveoli which are under-ventilated and relatively overperfused with blood.

This type of alteration leads to hypoxemia. There are areas that receive a blood supply and are completely unventilated since, in the very severe case, the arterial pO_2 does not go over 500 mm. Hg. even when the patient is breathing 100 per cent oxygen. That is, there are true right to left shunts within the lung in very severe or terminal cystic fibrosis patients. The end result of these abnormalities on the arterial blood in the moderately-severe case is an elevated pCO_2; if this is an acute case the pH may be decreased, but if there has been time for renal compensation the pH may be close to normal. The bicarbonate concentration may be normal or even increased, depending on renal compensation. The arterial pO_2 while breathing room air is decreased and, if severe enough, is associated with cyanosis. As I have mentioned, the PO_2 while breathing 100 per cent oxygen may be normal or decreased.

The frequent measurement of pulmonary function has been found to be of great help in cystic fibrosis patients, since it has been possible to predict incipient respiratory failure before there has been much clinical change. In other words, these tests, particularly the vital capacity and the measurements of the residual volume or functional residual capacity, have enabled us to see progression of the disease process and warn us that acute respiratory failure may occur. In these patients it has been possible to institute a vigorous therapeutic regime in an attempt to avoid the complication of respiratory failure.

Arterial Blood Gases

As I have indicated, one of the simplest, most inexpensive and useful tests of pulmonary function is the measurement of the vital capacity and one-second vital capacity. This measures many of the mechanical properties of the lungs but does not indicate how effectively our ventilatory efforts are in oxygenating the blood and removing carbon dioxide. Since the level of carbon dioxide in the blood is inversely proportional to the alveolar ventilation, the estimation of arterial PCO_2 is now commonly done in most hospitals. Probably the most widely used in children is the Astrup technique which requires only a couple of capillary tubes full of arterialized capillary blood for the estimation of arterial PCO_2 and pH, and an estimate of the metabolic component of the Henderson-Hasselbalch equation, the bicarbonate concentration. Not only does the estimation of the arterial PCO_2 tell us about the status of the alveolar ventilation in a particular patient, but it can also help us in estimating the alveolar oxygen tension which must be present.

The three component gases in the alveolar air are nitrogen, oxygen and carbon dioxide. Since nitrogen is inert, that is, not consumed, there is an inverse relationship between the partial pressure of carbon dioxide in the alveolar gas and the partial pressure of oxygen. The total of the two gas tensions must always, at sea level, be equal to approximately 150 mm. Hg. Thus, during normal alveolar ventilation when the arterial PCO_2 is approximately 40, the alveolar oxygen tension is approximately 110 mm. Hg. When alveolar ventilation is reduced, the arterial PCO_2 rises and the alveolar oxygen concentration must fall.

Knowing the alveolar concentration, however, one cannot predict with certainty the arterial oxygen concentration because right-to-left shunts, diffusion abnormalities, and ventilation-perfusion imbalance may all contribute to a gradient between the alveolar and arterial concentrations. Thus, to be absolutely certain, one must directly measure the arterial oxygen tension. However, one can say that the arterial PO_2 can be no higher than the estimated alveolar oxygen concentration. I must point out that these relationships are true only when the patient is breathing room air. When he is breathing 100 per cent oxygen the nitrogen concentration in the alveolar air is reduced and replaced by oxygen.

Summary

The pulmonary function laboratory has helped in our understanding in the pathogenesis of chronic childhood respiratory diseases and is used to evaluate the degree of functional abnormality and to assess our attempts at therapy. It is not possible, however, for all physicians to have access to large, expensively-equipped, sophisticated pulmonary function laboratories, but a great deal of information on a particular patient can be obtained by simple spirometry and by techniques for estimating the arterial PCO_2. Also, by the use of sophisticated techniques, it may be possible to predict and avoid respiratory failure in some of the chronic diseases of childhood.

The future course of the pulmonary function laboratory is predictably bright. Although there has been a tendency in the past to consider the lung as a simple elastic balloon, there is now a considerable body of evidence which indicates that the lung is a very active metabolic organ: the central clearance organ for many of the body's internal secretions, such as bradykinin, prostoglandins and other substances. In the future, respiratory physiologists will increasingly be considering the lung as an active metabolic organ, and it is by this sort of approach that our knowledge of the chronic respiratory diseases of childhood will be greatly advanced.

X-Ray Diagnosis in the Child[*]

JUSTIN WOLFSON, M.D.[†]
Minneapolis, Minnesota

THE X-RAY BEAM, as it transverses the chest, distinguishes four types of structure: calcium (bone), soft tissue (e.g., muscle, heart, fluid), fat (subcutaneous), and air (lung). The variable distribution of these densities on a plain film provides the means for radiographic diagnosis.

Because children grow, the roentgenogram of the chest progressively changes; however, a range of normal for varying age levels is recognized. Familiarity with the normal and its variations is requisite, for it permits recognition of the abnormal.

Steps in Diagnosis

Abnormal infiltrations of the lung may be produced by a bewilderingly large number of conditions. In order that these may be distinguished and a diagnosis achieved, the following steps are necessary:

Description

The lesion or lesions must be carefully and accurately described (location, size, contour, sharpness, multiplicity, calcification, associated disease, et cetera).

Correlation

The appearance of the lesion must be correlated with other factors: age of the patient, acuteness or chronicity ("timing"), alveolar or interstitial pattern, benign vs. malignant features and infectious character of the lesion. This process, if accurate, permits rapid exclusion of improbable diagnostic possibilities and the development of useful differential diagnoses.

The radiographic observations must be correlated with pertinent history, physical findings, and laboratory data.

---

[*] Presented at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

[†] Department of Radiology, University of Minnesota, Minneapolis, Minnesota.

Methods have been devised which, in an efficient and reproducible manner, attempt to exclude undesirable diagnoses and to provide ultimately an accurate diagnosis (see Table).

Chest Films

The chest film of the newborn may appear different on inspiration and expiration; the thymus gland is large, and artefacts, such as skin folds, can readily mislead the unwary. Certain diseases are characteristic of the newborn period: hyaline membrane disease, aspiration pneumonia, and diaphragmatic hernia.

Mediastinal Masses

It is convenient and useful to allocate mediastinal masses to one of three compartments: anterior, middle, or posterior. The contour, symmetry, presence or absence of calcification, and possible other associated findings, such as pleural fluid, should be observed. Benign thymoma, lymphosarcoma, teratoma, and primary tuberculous complex are well-known examples.

Increased Chest Volume

The volume of a hemithorax may be in-

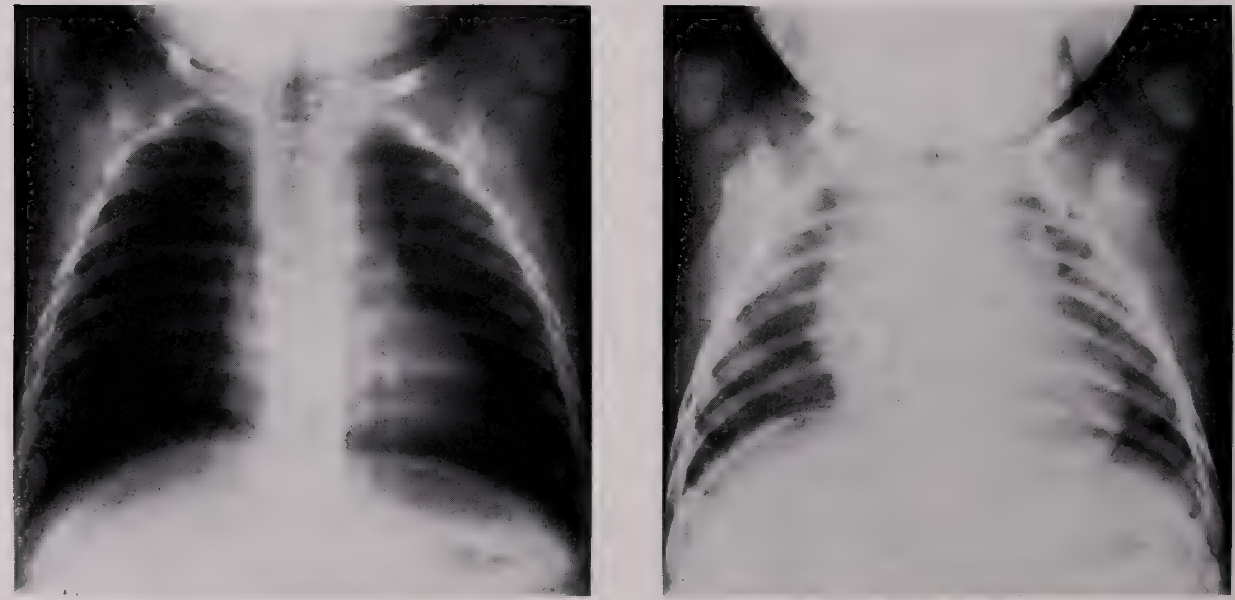

Figs. 1 and 2—Normal chest of an infant, inspiration and expiration films. On inspiration the right diaphragm lies at the level of the ninth to tenth posterior rib. On expiration the diaphragm lies at the level of the eighth posterior rib. With expiration the lung fields are hazy and the mediastinum is widened. This widening is due to the thymus gland, which may assume variable contours. On the right, at the level of the seventh posterior rib (Figure 2) the lower margin of the thymus forms a notch where it meets the true cardiac margin.

creased by (1) an increase in size of the lung from emphysema, (2) a growing mass within the lung or pleural space, (3) an extensive pleural effusion, with or without mass, and (4) tension pneumothorax.

Extrinsic compression upon or a foreign body within a bronchus may produce emphysema, not infrequently followed by atelectasis and even bronchiectasis. A lobe may continue to enlarge, producing compressive atelectasis of adjacent lobes and a shift of mediastinal structures such as in idiopathic lobar emphysema. Masses may extend the lung field from the mediastinum, chest wall, or diaphragm, or may lie free of these structures within the lungs.

Diminished Chest Volume

Chronic disease, such as may be associated with tuberculosis or lobectomy and pneumonectomy, or primary hypoplasia of the lung, may result in diminished volume. Each has features which are of aid in producing a specific diagnosis.

The Diaphragm

Masses may project through or originate from the diaphragm. The diaphragm may be eventrated on one or both sides or may appear to be eventrated when it is not, such as with diaphragmatic herniation or with collection of fluid between the lung and diaphragm (infrapulmonary effusion).

Interstitial Disease

Numerous disease entities affect the interstitial structures of the lung. Thus thickening of peribronchial and perivascular structures, of interlobular septate, and finally of alveolar walls occurs. Pure interstitial disease is distinctive in appearance. Since the process is subacute or chronic, an interstitial pattern serves as a timing device as well, and its presence allows us to exclude most alveolar (acute) processes.

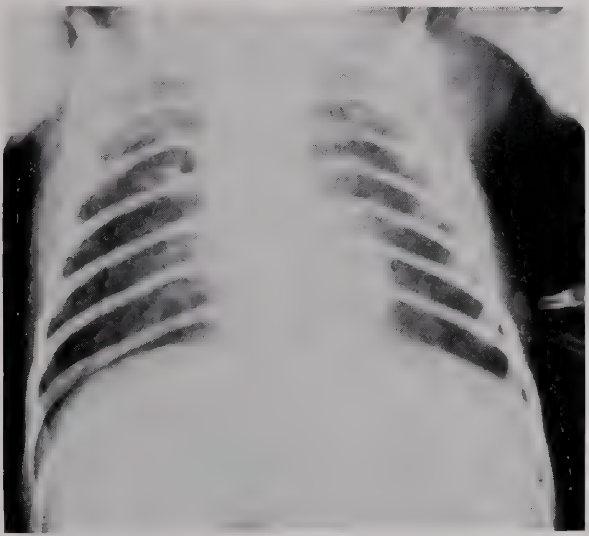

Fig. 3—Normal chest with vertical skin folds overlying right hemithorax. This appearance is produced by the juxtaposition of room air with a fold of skin while the infant lies supine upon the x-ray table. In this instance there are three such folds. The importance of such a fold is that it may simulate a pneumothorax, as does the most lateral of the three folds in this patient.

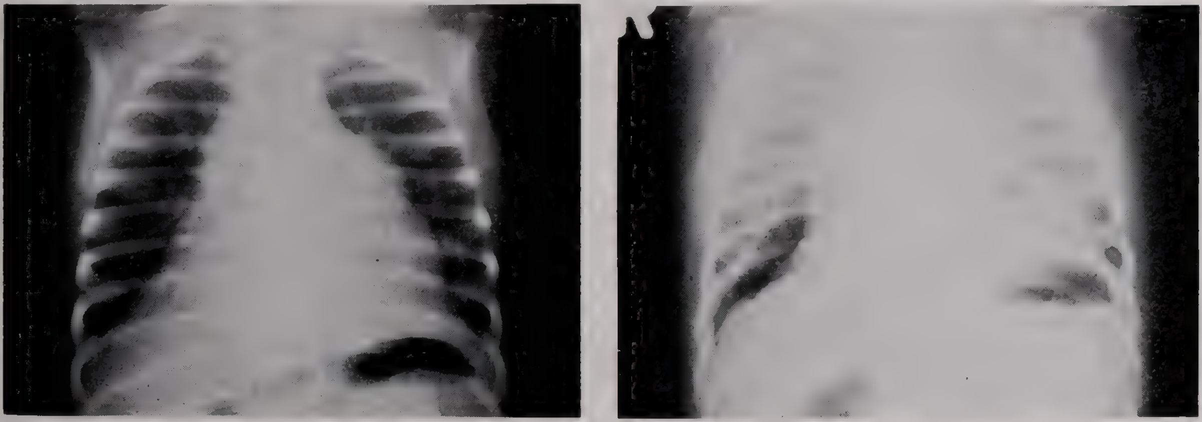

Figs. 4 and 5—Marked bilateral eventration of the diaphragms simulating cardiac or pulmonary disease. A normal cardiac silhouette overlies almost vertically oriented, sharply defined diaphragmatic leaves. In Figure 5 the full thickness of the diaphragms can be appreciated because air has been introduced into the peritoneal space. Actually a careful evaluation of contours and lung fields in Figure 5 alone permits one to exclude cardiac and pulmonary abnormality. However, as in this case, an eventrated diaphragm on one or both sides may produce diagnostic problems. Eventration, even as prominent as in this patient, rarely causes clinical symptoms. A sibling of this child also had bilateral eventration of the diaphragms.

Multiple Large Parenchymal Lesions

Multiple, large, spherical masses are usually interstitial and due to metastatic tumor, such as Wilms's. Multiple, rapidly enlarging, poorly defined masses, with or without excavation, suggest abscess formation.

Spherical radiolucencies, especially within an infiltrate, may be a tipoff to the presence of a staphylococcal pneumonia with pneumatocele. Occasionally, cavitation of a cyst or an abscess within a lobe of lung may be different to distinguish from a loculated hydro or pyopneumothorax. In such instances the absence of inflammatory changes in the remainder of the hemithorax tends to rule out an empyema.

Alveolar Disease

Normally the alveoli are air-containing. Any disease which permits the air within contiguous alveoli to be replaced by fluid of any sort will produce a characteristic opacification, which may be lobular, segmental, or lobar. Examples of extensive alveolar processes are lobar pneumonia, pulmonary edema, pneumocystis carinii, and pulmonary infarction.

There is nothing about the opacification which is distinctive except that it is alveolar. However, the distribution of the opacification and possible associated abnormalities usually lead to the correct diagnosis.

Alveolar disease may be spherical, but, unlike interstitial disease, it tends to be rapidly changing and therefore confluent. Thus, fat embolization with hemorrhage, chicken-pox pneumonia, and transfusion reaction may give this appearance.

Alveolar and interstitial processes may coexist and be difficult to distinguish from one another. Sequential films may be necessary for adequate interpretation. An example of a disease which often has a recognizable, interstitial component (due to chronic inflammation) and alveolar component (characteristically recurrent) is idiopathic hemosiderosis.

Conclusions

Radiographic patterns of pulmonary disease are a reflection of underlying pathologic processes, both gross and microscopic, and are useful in making diagnoses. However, they are not infallible. Equally important are the availability to the radiologist of pertinent clinical data and the opportunity for radiologist and pediatrician to peruse films together.

Biologic Peril

Abundance and affluence have brought new dangers of overweight, musculoskeletal problems from sedentary living, and skin disorders from sun bathing. Sociomedical prophets warn that man ignores his basic biological nature at his peril. The patient meanwhile protests the high cost of high quality medicine, sometimes looks on his physician more as a technician than an adviser, and demands powerful drugs for even his minor ills. At the same time complaints have been heard that the physician-patient relationship is becoming dehumanized; longings are aften expressed for the fatherly family physician of the past. As populations increase and medicine develops ever-greater technical refinements, a still more automated version of medical care, with punch-card case histories and diagnosis by computers hovers over the patient.*

Pulmonary Function Evaluation with ^{133}Xenon*

JOSE R. MEDINA, M.D.†
PHILIPPE L'HEUREUX, M.D.†
MERLE K. LOKEN, M.D., Ph.D.†
Minneapolis, Minnesota

THE IMPORTANCE of studying the relationships between pulmonary blood flow (perfusion) and pulmonary ventilation has been widely recognized. A variety of pathological disorders involving the pulmonary circulation or the broncho-alveolar structures produce changes in ventilation and perfusion which result in abnormal arterial blood gases. Since the pathology may be localized or diffuse, and since some disorders are amenable to surgery, it becomes increasingly important to identify their exact extent and location, and to determine the functional status of the remaining lung.

Bronchospirometry‡ and radioisotopic techniques have been used in regional evaluation of pulmonary function. Bronchospirometry, however, requires endotracheal intubation which limits its use; the simplicity of radioisotopic techniques makes regional evaluation of pulmonary function a practical clinical procedure. Various radioactive aerosols have been administered by inhalation and followed by scanning to study ventilation in the various areas of the lungs.[1,2] The techniques of lung scanning after the injection of macroaggregates of albumin tagged with ^{131}I or ^{99m}Tc have been used extensively in the study of the pulmonary circulation and in the diagnosis and follow-up of pulmonary embolization.[3,4] With the introduction of the radioactive gases xenon, krypton, and oxygen, the study of regional ventilation has become feasible;[5,6] this allows differentiation of diseases that affect the pulmonary vasculature alone, i.e., pulmonary embolism, from those that affect both perfusion and ventilation, such as pulmonary emphysema.

Materials and Methods

In 1955 Knipping and co-workers introduced ^{133}xenon for the study of ventilation and perfusion.[7] ^{133}Xenon is a chemically inert gas

---

†Departments of Medicine and Radiology, University of Minnesota.

‡See Test Your Word Score page 1401.

with a physical half-life of 5.27 days. Because of its solubility characteristics, it diffuses readily from the pulmonary blood into the alveolar air and is rapidly eliminated by the respiration. If the patient holds his breath after an intravenous injection of ^{133}xenon, redistribution of xenon does not occur and the pattern of radioactivity detectable by external monitors corresponds to the distribution of pulmonary blood flow. Ventilation is studied by inhalation of xenon gas from a closed circuit spirometer; the distribution of radioactivity indicates regional ventilation. The rate of clearance (washout) of the injected xenon from the lung is also a function of ventilation.

Diverse methods for quantitative analysis of ventilation and perfusion have been designed.[6,8] These methods compare the fractional counts recorded during the uptake and clearance of radioactivity by scintillation probes placed externally over the chest wall. With the Anger scintillation camera the distribution of ventilation and perfusion is displayed on scintiphotographs.[9] The gamma rays emitted from ^{133}xenon, administered by injection or inhalation, are displayed as flashes of light on an oscilloscope which is photographed with a polaroid camera. Sequential scintiphotographs are obtained during the uptake and clearance of xenon. Strip chart recordings are obtained of the uptake and clearance of radioactivity as displayed in each quadrant of the scintillation crystal. In addition, we have now installed interface equipment so that the data are recorded on magnetic tape for computer analysis. The computer program is written in a manner which permits an evaluation of ventilation and perfusion to be made on a regional basis.

Basic Patterns

Intravenous Xenon

Figure 1 shows the curves obtained with intravenous injection of 4 mc of ^{133}xenon. The upper tracing records the respiration, the lower a strip chart recording. The patient inspires slowly up to the point of maximal inspiratory capacity and holds his breath. A rise and plateau of radioactivity is recorded, corresponding to the xenon in the pulmonary circulation. The scintiphotographs obtained at this time show the perfusion to various areas of the lung. Once the patient resumes breathing, xenon clears from the lung as seen by fall-off of the radioactivity. The curve of xenon clearance is called the washout curve.

Inhalation of Xenon

Figure 2 shows a curve obtained from a strip chart recording after inhalation of xenon. The ^{133}xenon gas has been added to a closed circuit spirometer from which the patient takes a single deep breath up to his maximum inspiratory capacity and holds it while a plateau of radioactivity is recorded. He then resumes breathing of xenon gas in air which allows a uniform distribution of xenon throughout the lung. After "equilibration," a second plateau is recorded by again asking the patient to take

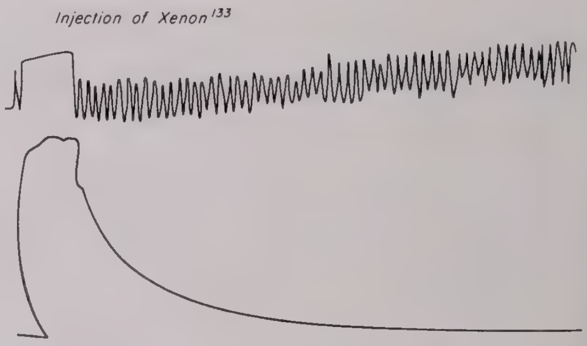

Fig. 1—Upper tracing records the spirogram; the lower, the uptake and clearance of ^{133}xenon injected intravenously. Notice that during breathholding a plateau is inscribed in the lower tracing. The distribution of radioactivity during this plateau indicates perfusion.

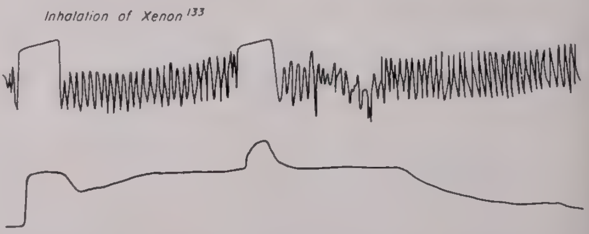

Fig. 2—Upper tracing records the spirogram; the lower, the uptake of ^{133}xenon during the inhalation of the radioactive gas from a spirometer. The first plateau corresponds to the distribution of ^{133}xenon after a single breath. A rebreathing period follows this initial breathholding to allow equilibration of the gas throughout the system. The second peak represents breathholding after equilibration and is used for correction of geometry and lung volume.

a deep breath to his maximum inspiratory capacity and to breathhold. The data obtained from this plateau is used for correction of lung volume and geometry.[6] Once a new base line is recorded the rebreathing of xenon is terminated and washout curves are recorded.

Results

In normal subjects studied in the upright position, the apices accumulate less radioactivity than the bases due to the effect of gravity on the distribution of blood flow.[10] The distribution of ventilation is more uniform, although there is proportionately less ventilation in the apices than at the bases. The clearance of xenon is also uniform. From the washout curves the rate of clearance can be measured; half of peak radioactivity after injection (T $\frac{1}{2}$) is cleared in 25 to 30 seconds.

Pathologically three patterns of abnormality of the distribution of blood flow and ventilation have been described: (a) abnormal perfusion with normal ventilation; (b) abnormal ventilation with normal perfusion; and (c) abnormal ventilation and abnormal perfusion. Individual patients may show various combinations of abnormalities. The following cases illustrate some of these changes.

Obstruction of Right Pulmonary Artery

Figure 3(b) shows the scintiphotographs obtained on a patient with obstruction of the right pulmonary artery. There are no scintillation events in the right lung. The ventilation photographs show that ventilation on the right side is preserved to some extent despite the absence of pulmonary blood flow. Some cases of pulmonary embolism also demonstrate preserved ventilation despite absent perfusion.

Bronchial Asthma

Patients with bronchial asthma have impaired ventilation with adequate perfusion,[11] and thus may present clinically with a low pO_2.

Most frequently poor ventilation and poor perfusion coexist, as seen in Figure 4. Notice that in the photographs the areas of poor perfusion initially show as dark areas and that

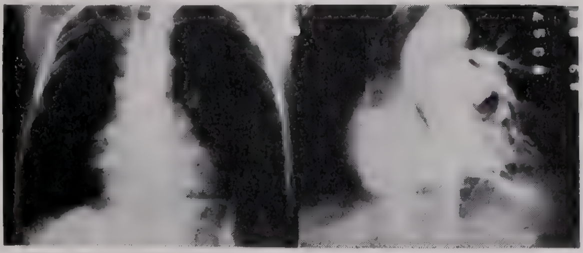

Fig. 3(a)—Chest x-ray and right ventriculogram in a patient with tetralogy of Fallot. The contrast material is seen simultaneously in the aorta and pulmonary artery because of right to left shunt through the ventricular septal defect. Notice that no contrast is seen in the right lung, indicating obstructed flow due to occlusion of the right pulmonary artery.

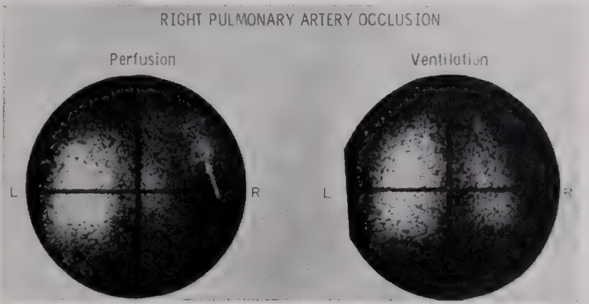

Fig. 3(b)—Perfusion-ventilation studies with ^{133}xenon of the patient in Fig. 3a. In the perfusion photograph there is a considerable decrease of radioactivity in the right lung (the reader's right) when compared with the left lung. The arrow points to radioactivity in the right arm. The ventilation photograph demonstrates relative preservation of ventilation in the right lung.

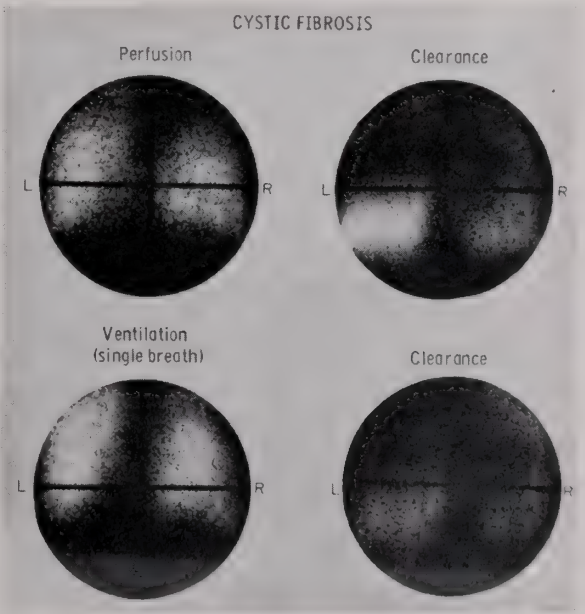

Fig. 4—Scintiphotograms of a 13-year-old boy with cystic fibrosis. The distribution of perfusion and ventilation is irregular with marked decrease in the left lower and right upper quadrants. Retention of radioactivity in the lower quadrants during the clearance phase indicates poor ventilation of these areas.

during clearance the same area is seen as a bright spot. This is due to retained radioactivity in poorly ventilated lung while the remainder of the lung has cleared.

A single intravenous injection of xenon permits study of perfusion (plateau) and ventilation (washout). In cases where inhalation is not possible the injection alone could detect areas of abnormal perfusion/ventilation as shown in Figures 5(a) and (b). The chest x-ray shows an area of hyperlucency with decreased bronchovascular markings, consistent with an emphysematous bulla. The injection of xenon demonstrates poor perfusion to this area, and the photographs during washout show the same area retaining radioactivity indicating poor ventilation as well.

Comments

Clinical Application

A practical application of regional ventilation and perfusion studies is the preoperative evaluation of patients where resectional lung surgery is contemplated. Figure 6 shows a patient with recurrent respiratory infections and bronchiectasis with roentgenographic evidence of destruction of the right upper lobe and changes in the left lower lobe which are not as well defined. The scintiphotographs show bilateral disease with poorly ventilated and poorly perfused areas in the left lower lobe as well as in the right upper lobe.

Insignificant Radiation

The radiation exposure in these procedures is low when compared with standard radiological techniques. The highest gonadal dose after the intravenous injection of 5 mc of ^{133}xenon has been reported to be 1 millirad,[12] which corresponds to the radiation dose from unavoidable cosmic radiation during about three days of life (at sea level). For the ventilation study with rebreathing, the calculated exposure is 35 millirads per minute, which is low compared with 3000 millirads per minute for fluoroscopic studies.

Summary

The technique of pulmonary function eval-

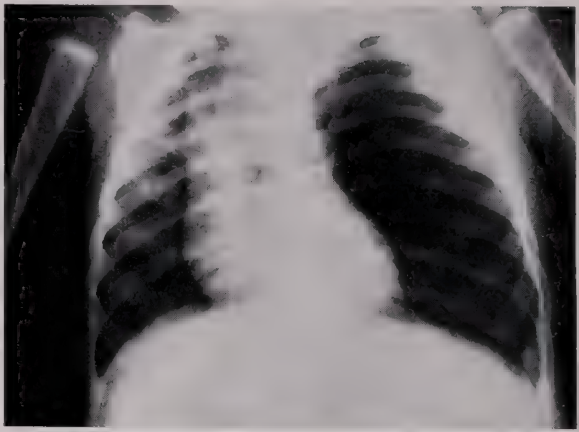

Fig. 5(a)—Chest x ray of a six-month-old patient. Notice the lack of bronchovascular markings in the left upper lobe and the mediastinal shift to the right.

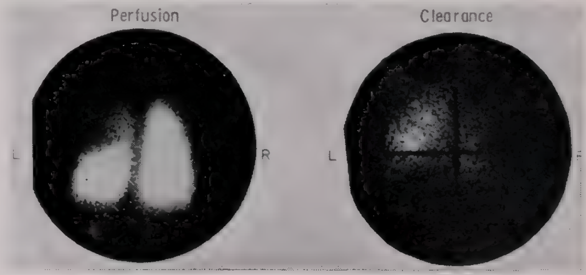

Fig. 5(b)—Scintiphotographs of patient whose chest x-ray is shown in Fig. 5a. The left upper lobe (the reader's left) shows decreased perfusion. The photograph taken during the clearance phase after the injection of ^{133}xenon shows radioactivity retained in the left upper lobe indicating poor ventilation.

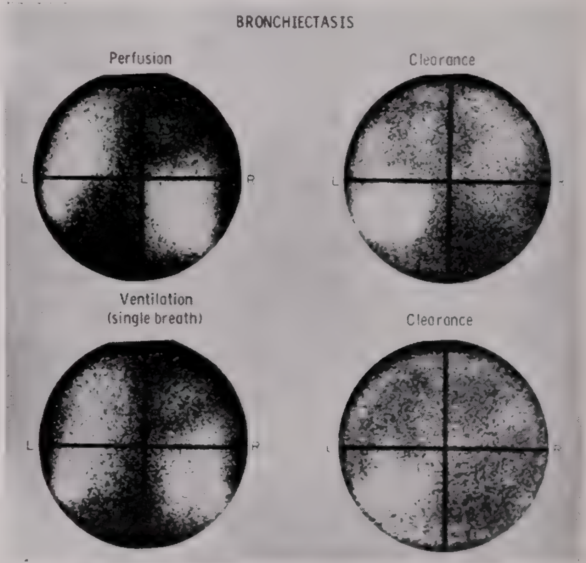

Fig. 6—Scintiphotographs of a patient with bronchiectasis in the right upper lobe and left lower lobe. Notice the lack of uptake in right upper (reader's right) and left lower (reader's left) quadrants in both the perfusion and ventilation photographs. The scintiphotographs obtained during the clearance of xenon show marked retention of radioactivity in the same areas.

uation with ^{133}xenon has been reviewed, and cases have been presented to illustrate some of the clinical applications. The advantages of the Anger scintillation camera have been described. It permits visual display of physiological phenomena, and topographic localization of functional abnormalities.

Bad Health and Big Shots

The specialists inform me that almost everybody had syphilis in the sixteenth century, including Henry the Eighth, who also endured chronic, malignant wife-trouble. Charles V, Holy Roman Emperor of the German people, was strong, cautious, brave and wise, but he ate too much. If he had had a passion for Wheaties instead of roast pig the destinies of Europe might have been quite different. Samuel Pepys, whose lady-killing tendencies are now blamed on a scar in his perineum, was presumably saddled with gall stones (many eighteenth-century surgeons carried handfuls of gravel around in their pockets for display purposes if an operation failed to produce stones).

Edward Gibbon had an embarrassing what-is-it dangling round his knees, unwieldy as his Roman Empire. Martin Luther struggled along for sixty-two years with nerve trouble, ear trouble, blood trouble, and heart trouble. Henry Fielding thumbed his nose at gout and dropsy and wrote "Tom Jones" and "Amelia." Alexander Pope had spells when he couldn't stand unless laced in a frame. He averred that, at a distance, he looked like a small windmill. The mere mention of Thomas De Quincey's ailments makes hardened medicos grow pale, and yet this strange genius kept plugging for seventy-five years.*

A hole is nothing at all, but you can break your neck in it.—Austin O'Malley

Minnesota State Board of Medical Examiners

Notice is hereby given that a public hearing will be held pursuant to Minnesota Statutes, Section 15.0412, Subdivision 4, in the above entitled matter, in the office of Minnesota State Board of Medical Examiners, 496 Lowry Medical Arts Building, Saint Paul, Minnesota, on November 8, 1969, commencing at 10:30 a.m. and continuing until all representatives of associations or other interested groups or persons have had an opportunity to be heard concerning adoption of the proposed amendments to the rules captioned above by submitting either oral or written data, statements, or arguments. Statements or briefs may be submitted without appearing at the hearing.

A copy of the proposed amendments to rules is listed below:

Minnesota State Board of Medical Examiners
By J. P. Medelman, M.D.
Secretary-Treasurer

I. Proposed amendment to Rule ME 2(b)(1).

Rule ME 2(b)(1) is hereby amended by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(1) If the applicant is a graduate of a medical or osteopathic college approved by the Board, original or certified copy of diploma from such medical or osteopathic college, as the case may be, indicating that the applicant has satisfactorily completed a course of study acceptable to the Board and that he has received from such college the degree of Doctor of Medicine or Doctor of Osteopathy."

II. Proposed amendment to Rule ME 2(b)(2).

Rule ME 2(b)(2) is hereby amended by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(2) If the applicant is currently enrolled in the final year of study at an approved medical or osteopathic college, a transcript of his credits, together with evidence, satisfactory to the Board, that the applicant has satisfactorily completed the course of study prior to such final year at an approved medical or osteopathic college. Prior to admission to the licensing examination, the applicant shall file with the Board the original or a certified copy of a diploma from a medical or osteopathic college approved by the Board indicating that the applicant has satisfactorily completed a course of study acceptable to the Board and that he has received from such college the degree of Doctor of Medicine or Doctor of Osteopathy."

III. Proposed amendment to Rule ME 2(c).

Rule ME 2(c) is hereby amended by striking and deleting therefrom the words "Bachelor of Medicine, Bachelor of Medicine and Surgery".

IV. Proposed amendment to Rule ME 4(b)(2).

Rule ME 4(b)(2) is hereby amended by striking and deleting therefrom the words "Bachelor of Medicine, Bachelor of Medicine and Surgery".

V. Proposed amendment to Rule ME 11(g).

Rule ME 11(g) is hereby amended by adding after the word "revoke", the following words: "suspend, condition, limit, qualify, or restrict the license of,".

VI. Proposed amendment to Rule ME 11(g)(1).

Rule ME 11(g)(1) is hereby amended by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(1) Conviction of the crime of criminal abortion or of a crime involving moral turpitude."

VII. Proposed amendment to Rule ME 62.

Rule ME 62 is hereby amended by adding after the word "suspended", the following words: "qualified, restricted,".

VIII. Proposed amendment to Rule ME 70(a).

Rule ME 70(a) is hereby amended by adding thereto after the word "limited", the words "qualified, restricted,".

Physical Conditioning Course for Children with Asthma

THE CHILD WITH asthma presents an unusual therapeutic situation. Both specific and non-specific factors must be considered in the complete management of such a child.

Allergy to a particular substance is considered a specific factor. Non-specific factors include infection, physical condition, posture, breathing methods, irritating substances and emotions.

The non-specific factors may irritate, aggravate, and complicate the course of asthma. Their management is often just as important as that of the specific allergen.

Realizing that the child with asthma is a concern not only to himself and his family, but to everyone who associates with him, the Respiratory Disease Association of Hennepin County began investigating the problem in the fall of 1965.

The Medical Advisory Committee of the Respiratory Disease Association of Hennepin County agreed, however, that more could be done for the child with asthma, particularly in relation to non-specific factors, i.e., by strengthening him physically and emotionally. This was borne out through an investigation of previous studies of children with asthma.

Feeling that a "Physical Conditioning Program for Children With Asthma" would serve the community and be a logical step for a voluntary agency to take, the Medical Advisory Committee considered a plan and its implementation. Of major significance, the prototype plan stipulated that the program was not to be considered as treatment, but as an adjunct to treatment, and that admission to the program would be only upon private physician referral. To date 162 out of 172 children who have registered have completed the course.

A $15.00 registration fee is charged to help defray the cost of the program and to obligate participants to attend regularly. In cases where the participant is unable to pay, the Respiratory Disease Association absorbs the cost.

The program has three main goals. The first goal is the improvement of the physical fitness of the participants. The youngsters are taught to breathe correctly and to improve their coordination and posture.

The second goal is of a psychological nature. The program is structured to allow the child with asthma to help himself, thus decreasing his dependency on others. As he increases his ability to do breathing exercises, he is learning how to diminish the shortness of breath associated with his asthma, thus reducing his fears and anxieties.

All too often, the child with asthma is looked upon as being "different" by himself, friends, family, and the community. As a result, his participation in society is less than optimal. Therefore, the third objective of the program is the education of the child, parent, and community to give a better understanding of the disease and its care.

Classes are held throughout the school year in the late afternoon or evening. Sessions last two hours, once a week, for eight weeks. Classes have been held at Fairview Hospitals, North Memorial Hospital, Glenwood Hills Hospital, Methodist Hospital, Ascension Club, and Penn Junior High School in Bloomington. Each class is geared to a specific age group: four to five years, six to eight years, nine to 12 years, and teenage.

Last fall, for the first time, behavior profiles were begun on the children prior to the first class, at the completion of the course, and at three, six, and 12-month intervals following the class.

The program consists of planned activities for both the children and the parents. The exercise program for the youngsters includes four phases, depending upon the location and age group:

1) Specific breathing exercises and general body conditioning
2) Karate instruction
3) One-half hour sessions in the swimming pool
4) Group discussions about asthma

For the specific breathing exercises, a two-pound sandbag is placed on the child's abdomen to demonstrate which muscles should be used in correct abdominal breathing. The child is told to inhale, lifting the sandbag up for a count of two, and then exhale, making a loud hissing sound through the teeth, for a count of six.

Most of the general conditioning exercises and calisthenics are the same as those used in school physical education programs. An exercise record book is given to each child and is used to record the number and type of exercises done each week. The record book is checked at the time of the weekly class session.

The second phase of the program is karate instruction, conducted by a qualified karate instructor and designed to improve self-confidence, coordination, and just for fun.

The third phase of the program is swimming. If a child does not know how to swim and wishes to learn, a qualified instructor works with him. Several have learned to swim during the class sessions, but the degree of success varies considerably. The purpose of including swimming in the program is to have the children feel relaxed and comfortable in the water. The general impression is that they enjoy the swimming phase of the program more than the exercises. It actually serves as a reward for exercising.

There are some definite conclusions and several impressions that can be drawn from the program to date. Almost all the children improved in some way, and very few have experienced unfavorable symptoms during the course. The majority demonstrated an increase in tolerance for exercise and activity participation. Several swam for the first time and several started to play Little League baseball. Others commented that they were able to participate in gym regularly for the first time. A significant number of the children need less medication than in previous years. Also, there has been improved school attendance, compared to a similar period during the previous year.

Children who graduate from the program are eligible to attend Camp SDIKREPUS ("superkids" spelled backwards). Camp SDIKREPUS is a two-week, away-from-home summer camp that is aimed at providing a well-rounded camping experience for the child with asthma—who very seldom is allowed to go to camp. At this point, we have three years of camping experience under our belts and are looking forward to next year.

In summary, the "Physical Conditioning Program for Children with Asthma" has been successful. The future of the program? That depends on the Medical Advisors who meet monthly to evaluate and refine the total program. Everyone involved in planning and implementing the course agrees that the program has fulfilled a real community need and that the program is a logical step for a voluntary agency to take.

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol. An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take. PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Parke, Davis & Company
Detroit, Michigan 48232

PARKE-DAVIS

symptoms of mixed anxiety-depression are rarely clear-cut.

but they are often a clear indication for

Mellaril®

(thioridazine)

25 mg. t.i.d.

effective in mixed anxiety-depression and in moderate to severe anxiety

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

SANDOZ PHARMACEUTICALS, HANOVER, N.J. SANDOZ 69-384

Office Diagnosis of Immunologic Deficiency*

RICHARD HONG, M.D.†
Minneapolis, Minnesota

THE TRADITIONAL teaching that infection is the most important thing in alerting one to the diagnosis of immunologic deficiency is not a fruitful approach. If a child has a history of recurrent pulmonary infections, it is much more likely that he has a basic allergic diathesis rather than an immunologic problem. Other clues to an accurate diagnosis as itemized in the Table may not occur as often but, when encountered, are of much greater significance. For example, chronic moniliasis of the oroficial areas suggests the serious lymphopenic form of agammaglobulinemia in which the cellular immunity is deficient; this fatal form is also suspected if a child has progressive vaccinia. Chronic diarrhea or ulcerative colitis, especially if it occurs in the first year of life, may herald agammaglobulinemia. There are now four cases reported in which severe lymphopenic agammaglobulinemia is associated with short-limbed dwarfism.

Laboratory Studies

Hematological disorders have not been stressed as a clue to the diagnosis of immunologic deficiency; yet in recent years we have picked up countless cases of immunologic deficiency by having an immunologic study done on children who presented originally with a hematologic disorder.

Thrombocytopenia and Lymphopenia

Thrombocytopenia demands an immunologic investigation; immunologic deficiency is virtually the only cause of lymphopenia in a child other than some leukemias or Hodgkin's disease. In the newborn, lymphopenia essentially means the Swiss form of agammaglobulinemia which was, until recently, a uniformly fatal disease. There are a few pitfalls involved in the assessment of lymphopenia because the lymphopenia that we worry about is that involving the small lymphocytes. Many of the affected children have medium-sized lymphocytes and may have a total lymph count within normal (1500 total or more). Monocytosis and eosinophilia of about 10 or 15 percent should also alert suspicion. I know of no condition in the newborn period or first few months of life where you find the combination of monocytosis and eosinophilia. When you see this, even if the lymphocyte count is normal, you should look at the smear yourself; you will probably note that the lymphocytes are all of the large variety and not the little "ink dot" type.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Department of Pediatrics, University of Minnesota, Minneapolis, Minnesota.

Chest x-rays which show persistent pneumonia, chronic pneumonia or absence of the thymic shadow indicate immunologic deficiency.

Physical Examination

The physical examination reveals lymphoid hypoplasia. A child who has true agammaglobulinemia will not have enlarged lymph nodes and the pharyngeal tonsils will not be enlarged. General growth and development are normal. It is very interesting that children who have really severe frequent infections do not have growth retardation. Our hypogamma patients are often big strapping individuals.

Telangiectasia, especially of the eyes and ears, will be found in patients with ataxia-telangiectasia, and the syndrome here would include chronic sinusitis, bronchiectasis and usually some ataxia. Sixty percent of these show an immunoglobulin A deficiency and usually go on to have a fatal outcome after a long progressive downhill course.

Laboratory Diagnosis

Traditionally paper electrophoresis has been used to diagnose agammaglobulinemia, and it is unfortunate that many children are started on gammaglobulin therapy, using paper studies as criteria for diagnosis. Tragic complications can result: some of these children develop emotional problems and the parents acquire financial problems as the result of a mistaken diagnosis of hypogammaglobulinemia. Paper electrophoresis is worthless for the diagnosis of immunologic deficiency; it is used simply because it is readily available. Unfortunately, too many physicians shy away from an immunologic technique because they think that one has to have a $50,000.00 laboratory and a $35,000.00 technician. In fact, all one needs is $13.00 for a commercially prepared agar plate. Then all that is necessary is to draw blood or take capillary blood from the fingertip, spin it down in a hematocrit tube and break off the red cells, and then use them to fill small wells, which are already cut in the agar. The test can be done by any practitioner anywhere and is perfectly reliable. Standards from one commercial source to another may show a great deal of discrepancy; however, one is usually not as interested in hypergammaglobulinemia as in hypogammaglobulinemia. The critical level for immunoglobulin G is around 200 mg %. For immunoglobulin A and immunoglobulin M there is no need to make a decision about "borderline" values; children who have significant disease have nearly zero values (~10mg%).

Uncertainty concerning the significance of immunoglobulin values can be resolved by functional assays: measurement of specific antibody levels or titers. The development of an antibody against a known antigen proves the competence of all facets of the immune system, viz., the uptake, recognition and processing of the antigenic material followed by appropriate protein production in response to this stimulus. We commonly employ the following assays for convenience. A Schick test is easily performed and nearly all children in this country have received the appropriate immunizing series. The reagents are available from any pharmacy. In addition, isoagglutinins can be measured; the normal levels are usually ~1:20 . Further corroboration of antibody results can be obtained by immunizing with typhoid-paratyphoid antigens in the usual dosage schedule (0.5 ml sub-Q at one-week intervals for three doses). Following the immunization, most state or hospital laboratories can

TABLE

Clues to Immunologic Deficiency—History
- Recurrent Infections
- Hematological Disorders
- Skin problems—atopic dermatitis, progressive vaccinia
- Chronic diarrhea
- Ulcerative colitis
- Persistent oral moniliasis

assay for Salmonella antibodies which will be present in high titer (greater than 1:160). The value of these types of corroborative assays is illustrated by the findings in a hypogammaglobulinemic state unassociated with immunologic deficit, such as nephrosis. The gamma globulin levels in lipoid nephrosis are frequently below 200 mg%; yet with stimulation the antibody response is as high as in those patients whose gamma levels are normal. In other words, the total immunoglobulin level is less important than the specific antibody response as an indicator of immunological competence.

In a similar way, we can assess cellular immunity; we usually rely upon the standard skin tests such as the Mantoux reaction for this. The antigens employed are Old Tuberculin or Purified Protein Derivative, Candida, streptokinase-streptodernase (Varidase®) and are read at 48 hours; ten mm of induration and erythema should be present for a positive test. Unfortunately, in many instances the patient has not had a previous infection and the tests are normally negative. In this case, an actual count of the number of *small* lymphocytes is helpful. Normally, children will have over 1500 small lymphocytes/mm^3. Other assessment of the cellular system requires specialized laboratory facilities and is not within the province of the usual clinical laboratory.

Conclusions

Office diagnosis of true immunologic deficiency is feasible, and the practitioner can provide a real service and save many children from needless gamma globulin injections.

19th Century Failures

Beethoven

One celebrated patient whom medicine could not help was Ludwig von Beethoven. Plagued by intestinal disorders and approaching deafness, he made a fruitless round of physicians and surgeons, took baths, pills, and poured medications into his ears. His final illness twenty-three years later began with pneumonia after a carriage ride on a bitterly cold day but soon changed to symptoms of liver disease, which he had probably suffered from youth. His physician administered large doses of orchid tubers and repeatedly performed paracentesis. Beethoven bore his sufferings with heroic calm, but death came three months after the onset of illness. Autopsy confirmed the diagnosis of hepatic cirrhosis but showed no trace of the syphilis he had suspected to be the cause of his deafness.*

---

*The Patients' Progress, Edited by Felix Marti-Ibanez, 1962.

Editor's Note: I don't suppose that the orchid tubers did much good but no doubt the paracentesis relieved him of the distress associated with his liver cirrhosis, which could have resulted from his longtime imbibing of the spirits at his numerous social activities.

O.W.H. to the Young Practitioner

You cannot and need not expect to disturb the public in the possession of its medical superstitions. A man's ignorance is as much his private property, and as precious in his own eyes, as his family Bible. You have only to open your own Bible at the ninth chapter of St. John's Gospel, and you will find that the logic of a restored patient was very simple then, as it is now, and very hard to deal with . . . Lord Bacon, Robert Boyle, Bishop Berkeley, all put their faith in panaceas which we should laugh to scorn. They had seen people get well after using them. Are we any wiser than those great men?*

---

*Oliver Wendell Holmes

Epitaph: a belated advertisement for a line of goods that has been permanently discontinued.—Irvin Cobb

King James I

Walking Pathological Museum

James was afflicted with the normal gigantic appetite of kings in those days. He ate anything and everything so long as it could be eaten; not even Charles V could have excelled his prowess. He drank, indiscriminately, beer, spirits, Spanish wines, cider, sweet French wines, and muscatel, probably mixing them all right royally. His interior organs were always too full, and he got rid of the vast surplus in whatever disgusting way, up or down, happened to be convenient.

He was subject to catarrh, and was much affected by cold and damp; he was constantly spitting, hawking, and blowing his nose. As handkerchiefs were not then in general use, I have heard that he used his sleeve or his finger and thumb, which would not add to his "clubability." He had some difficulty in swallowing, owing to some narrowing of his fauces, inherited from his mother, Mary Queen of Scots, and from his grandfather, James V of Scotland. Putting two and two together, the constant blowing of his nose and the "narrowing" of his throat, one imagines that probably the poor man suffered from adenoids and enlarged tonsils. He occasionally suffered from gravel, often accompanied by blood. He constantly suffered from another ignoble trouble, which in the course of years bled copiously. If he was specially worried in mind or body—and a king is always worried—he would become jaundiced. Whenever anything more than usually alarming occurred, the unhappy man would get diarrhoea, just like an anxious student awaiting his interview with the examiners. He used faithfully to insist on his being bled every day, until his least dignified ailment saved the doctors the trouble.

He had a truly psychasthenic dread of pain, yet hated all doctors, possibly because he had suffered too much at our hands. His teeth were all decayed, so that he could chew nothing, but had perforce to bolt his food. A man with the decayed teeth that so distinguished the "most learned fool in Christendom" would naturally in time suffer from arthritis; and in middle age this complaint so crippled him that he could hardly mount his horse. He detested purgatives, and considered that any medicine, to do good, must act upon the bowels without griping the patient; till late in life he would not even allow an enema, probably because it hurt him.

With death came, as usual, a little of that dignity that was so sadly lacking in his life. S. R. Gardiner says that he died of a fever, but it is impossible even to guess at its nature.

They held a post-mortem examination upon him, because there were the usual accusations of poisoning, apparently founded largely upon the swelling of his tongue. They found that his heart was enormously enlarged, and that in his left kidney, which was greatly shrunken, there reposed two stones, from which doubtless had come that gravel which had so afflicted him during his life. Possibly his enlarged heart and swollen tongue, together with his vast overeating and drinking, may have meant that King James I had chronic Bright's disease.*

---

*C. MacLaurin: Post Mortems of Mere Mortals, 1925.

Editor's Note: With a history like that, to the diagnosis I would have added: massive obesity, hypertension, cirrhosis of the liver, esophageal varices and cardiospasm. Whatever his ignoble, least dignified trouble was could offer numerous interesting speculations.

Allergic Pulmonary Disease*

Criteria for the Diagnosis

STUART L. AREY, M.D.[†]
Minneapolis, Minnesota

BRONCHIAL ASTHMA is a form of pulmonary functional derangement resulting from reversible obstructive hyper-inflation of both lungs and characterized by paroxysmal episodes of cough and dyspnea and a prolonged expiratory phase with wheezing. Early attacks are typically relieved by sympathomimetic[‡] drugs. There may also be spontaneous remissions. The syndrome may be acute or chronic, seasonal or perennial, of single, multiple, or unknown etiology. The American College dictionary defines a wheeze as "to breathe with difficulty and with a whistling sound."

Stages of Asthma

Asthma usually presents with subjective symptoms of coughing and tightness in the chest, followed by progressive dyspnea, whistling, and expiratory wheezing until the height of the attack is reached. There are four types: I. In the simplest form there is only coughing which may be present as intermittent episodes and may persist for years. There may or may not be multiple musical expiratory rales present. II. The patient has classic symptoms with complete freedom in the intervening periods. III. The patient is always symptomatic, but there are acute exacerbations lasting two to five days. IV. There is constant severe asthma with minor changes in intensity of symptoms.

Stage I is a precursor of typical asthma. It merits good care and is not to be dismissed in the prescription for a favorite cough medicine. Some may prefer a diagnosis of allergic tracheobronchitis to avoid the stigma of a diagnosis for a time.

Etiology

Pollen

Pollen patients are worse outside, better inside, worse on bright sunny days, and have itchy eyes. In Minnesota the primary pollen is ragweed which blooms from the middle of August to frost. Grass is important in June. Tree pollens begin with elm about March 31 and end late in May. The secondary pollens, i.e., those which add to the total allergic load but do not cause symptoms by themselves, are Kochia, chenopods, Russian thistle, plantain and sorrel which bloom during the summer.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

[†] Department of Pediatrics, University of Minnesota.

[‡] See Test Your Word Score page 1401.

House Dust

Housedust antigen is either the breakdown product of cotton or a parasite. It is most important when the house is closed, i.e., from September to April with the peak in January and February. These patients are worse inside, better outside. Their eyes don't itch. They tend to be worse within an hour of the time they go to bed. The mattress is a prime generator of housedust antigen.

Molds

Mold patients are worse in damp weather, worse in the low places in the road, worse in the "cool of the evening," and have symptoms after the ragweed season. They also tend to be worse when playing in the grass. There are seasonal peaks during the summer and fall. The molds disappear only when the ground is covered with snow. The primary molds in Minnesota are Alternaria and Hormodendrum. The complete list is almost endless.

Animal Emanations

Of the animal emanations, cats and dogs are most important; but cats are worse offenders than dogs because children invariably hold a kitten or cat under their nose and do a provocative test.

Foods

Foods are suspected if there is a monotonous regularity of symptoms, regardless of changes in weather, activity, or time of year. These patients tend to get worse in the middle of the night. They may have itching of the back of the nose or throat: a symptom which is almost never volunteered. Food sensitivity may be perennial, concomitant or thermal. Perennial patients have symptoms regardless of season. Concomitant food sensitivity refers to patients who have troubles only during the pollen season. Thermal food allergy is a sensitivity related to a specific food which reacts when the temperature falls below a certain level.

Family History

Over half of the children with asthma will have a positive family history of allergic disease. There seems to be a mental block about allergic disease. Superficial questioning such as: "Does anyone in your family have allergic disease?" will often fail to uncover a positive family history.

A history of previous atopic disease will favor a diagnosis of asthma: colic, spasmodic croup, infantile eczema, feeding difficulties, excessive perspiration, cracks behind the ears, itching of the nose or throat, allergic salute, perennial allergic rhinitis, seasonal pollenosis, or urticaria.

A history of sudden onset of wheezing without previous allergies is suggestive of a foreign body.

Physical Findings

In asthma we expect multiple expiratory rales throughout the chest. These rales are caused by forced expiration with the mouth open.

In mild cases they are best heard in the right anterior chest at the midclavicular line at about the level of the third or fourth rib. In long-standing severe asthma, the typical barrel chest is seen.

One of the most valuable differential points in uncomplicated asthma is the absence of clubbing of the fingers seen in contrast to the common presence in cystic fibrosis with severe pulmonary involvement.

Asthma in children under two differs from that seen in older children. Infants under two will lie on their back with marked asthma but do not exhibit the subjective distress of older children. The older child will invariably sit up and lean forward with his shoulders hunched forward during a severe attack.

Laboratory Tests

Other speakers have discussed pulmonary function, sweat tests, blood gases, eosinophilia and x-rays of the chest.

Skin Tests

Skin tests are very helpful in confirming a diagnosis of allergic disease. Scratch tests are approximately 1/100 as sensitive as intradermal tests. Either intradermal tests starting with a weak dilution as advocated by Rinkel,[1] or preliminary scratch tests followed by intradermal testing should be done. The tests for inhalants, when correlated with the history, are quite accurate; however, a few individuals will have a positive skin test for a pollen only during the pollen season.

Individual Food Test

Scratch tests or intradermal tests for foods are only 30% accurate either in a positive or in a negative fashion. Probably the most accurate test is Rinkel's individual food test. This is performed by omitting the food to be tested in all forms for four days and then feeding the food as the second meal on the fifth day, under test conditions, and noting its effect. Each test requires four days of preparation and two hours of observation. Rinkel's provocative food test is performed by injecting 0.1/ml. of a 1:100 food extract in two sites intradermally and observing the effect in twenty minutes. This test correlates well with individual feeding tests and enables one to test more foods in a shorter time with 80-90% accuracy.

Differential Diagnosis

The almost endless list can be divided with the other causes of wheezing: inflammatory, mechanical, metabolic, neurologic, and traumatic.

The following is an outline of non-allergic causes of wheezing in infants and children. The most important causes are starred.

Inflammatory:

1. Retropharyngeal abscess or peritonsillar abscess, 2. laryngitis-diphtheric or non-diphtheric, 3, epiglottitis, 4. laryngotracheobronchitis, 5. spasmodic croup, *6. asthmatic bronchitis, 7. bronchiestasis, 8. pneumonitis, *9. cystic fibrosis, *10. bronchiolitis.

Mechanical Obstruction:

1. Enlarged adenoids, polyps of the nose and larynx, 2. mucus vibrating in the respiratory passages, 3. extrinsic compression as lymph nodes or foreign body in the esophagus, *4. intrathoracic obstruction, such as a foreign body, *5. cardiovascular obstruction, such as a vascular ring and anomalies of the great vessels, 6. congenital anomalies of the respiratory tract: choanal atresia, tracheal stenosis, bronchostenosis, flaccid epiglottis, tracheomalacia, cysts of the thyroglossal duct, redundant folds of mucous membranes, subglottic hemangioma, congenital web larynx, lobar emphysema, bronchopulmonary sequestration, agenesis of lobe of the lung.

Metabolic:

Stridor of tetany.

Neurologic:

Paralysis of the recurrent laryngeal nerve and the stridor of cerebral palsy.

Traumatic:

Dislocation or fixation of the cricoarytenoid joint.

Summary

Bronchial asthma is a form of pulmonary derangement resulting from reversible obstructive hyper-inflation of both lungs. It must be differentiated from other forms of obstructive pulmonary disease, especially cystic fibrosis and foreign bodies. A family history of atopic disease is often uncovered. The chronology of the attacks should correspond with skin tests. Skin tests for inhalants correlate well with history. Skin tests for foods are only 30% accurate in either a positive or a negative fashion. The provocative food test has been very helpful in practice.

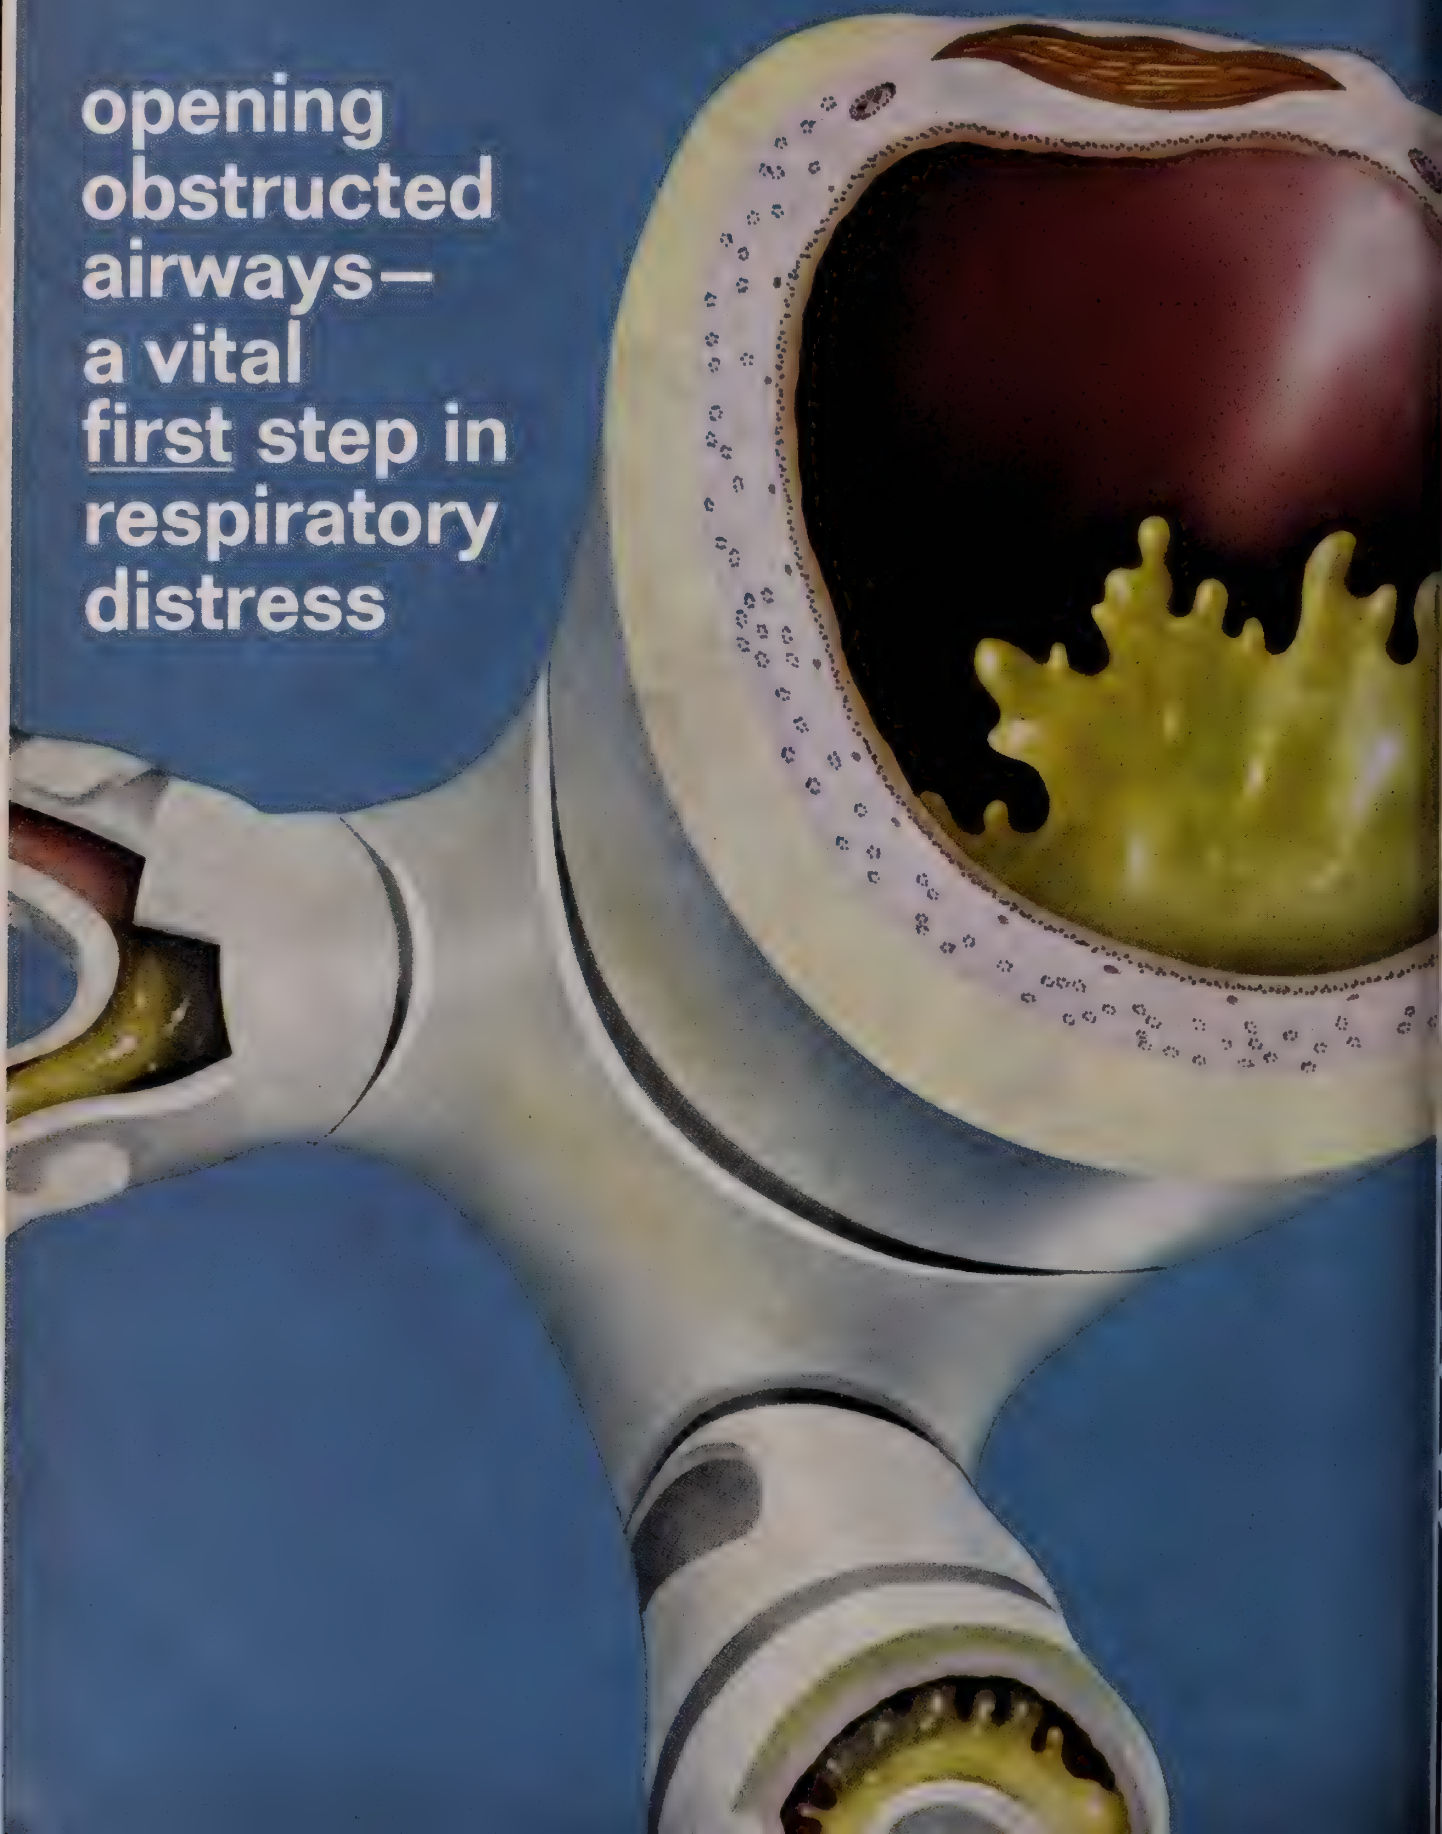
We do not admire what we cannot understand.—Marianne Moore

Mead Johnson—pharmaceuticals created for your specialized clinical needs



opening obstructed airways— a vital first step in respiratory distress

effective mucolysis with proved safety

MUCOMYST®

(ACETYLCYSTEINE)

liquefies tenacious mucus that complicates recovery in hospitalized patients

"Continuous efforts to maintain the patency of the airways by removal of secretions is the basis of good [bronchopulmonary] management."*

Mucomyst liquefies both purulent and nonpurulent mucus to help clear mucus-obstructed airways and aid in maintaining adequate ventilation in a wide range of bronchopulmonary conditions.

The selective effect of Mucomyst upon mucoprotein is not enzymatic. It is believed to act by breaking the disulfide bonds—"the structural cement"—of the mucoprotein molecule.

The molecular structure is altered without breaking the main protein chain. Mucomyst does not damage mucous membranes or lead to the formation of sensitizing polypeptides.

In vitro studies have shown Mucomyst to be more effective than saline solutions, proteolytic enzymes, or detergents in reducing the viscosity of mucus obtained from patients with various types of pulmonary disease.

> Now a new 10% solution, Mucomyst-10, offers you the choice of prescribing a lesser concentration whenever you feel this is desirable. It provides added convenience and simplicity, particularly for your patients using nebulizing units at home.

Indications: Mucomyst has been demonstrated to be clinically effective adjuvant therapy in a wide range of conditions in which thick, viscous mucus is a problem, including: postoperative atelectasis and pneumonia; chronic bronchopulmonary disease (emphysema, chronic bronchitis, asthma, and bronchiectasis); acute bronchopulmonary disease (pneumonia, bronchitis, and tracheobronchitis); tracheostomy care; facilitation of bronchial studies; maintenance of an open airway during anesthesia; and to help control pulmonary complications of cystic fibrosis. **Contraindications:** Mucomyst is contraindicated in those patients who are sensitive or who have developed a sensitivity to it. **Warnings: After proper administration of acetylcysteine, an increased volume of liquefied bronchial secretions may occur. When cough is inadequate, the open airway must be maintained by mechanical suction if necessary. When there is a large mechanical block due to foreign body or local accumulation, the airway should be cleared by endotracheal aspiration, with or without bronchoscopy. Asthmatics under treatment with Mucomyst should be watched carefully. If bronchospasm progresses, this medication should be immediately discontinued. Adverse Reactions:** Adverse effects have included stomatitis, nausea and rhinorrhea. Sensitivity and sensitization to Mucomyst have been reported very rarely. A few susceptible patients, particularly asthmatics (see Warnings), may experience varying degrees of bronchospasm associated with the administration of nebulized acetylcysteine. Most patients with bronchospasm are quickly relieved by the use of a bronchodilator given by nebulization. **Administration & Dosage:** Mucomyst may be administered by nebulization into a tent, Croupette, face mask, or mouthpiece; or by direct instillation. **Mucomyst should not be placed directly into the chamber of a heated (hot-pot) nebulizer.** Complete details on dosage, administration, and compatibility are included in the package insert. Additional information may be obtained from Mead Johnson Laboratories. **Supplied: Mucomyst (acetylcysteine),** a sterile 20% solution, in vials of 10 ml. and 30 ml.; and **Mucomyst-10 (acetylcysteine),** a sterile 10% solution, in vials of 10 ml. and 30 ml.

For elderly patients
in need of a mild tranquilizer
consider **Tybatran**®
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

How Cystic Fibrosis Can Be Confused with Chronic Bronchitis and Bronchial Asthma*

WARREN J. WARWICK, M.D.†
Minneapolis, Minnesota

THE CLINICIAN IS HANDICAPPED by the words he uses for these diseases. The terms "asthma" and "bronchitis" derive from Greek words, both have existed in lay and professional vocabularies from antiquity, and both carry vague connotations. Despite attempts to promote clear definitions, both terms are frequently used to describe a disease, a clinical state, a symptom, or a sign.

Asthma and Bronchitis

Asthma, when used as a designation for a disease, is equivalent to allergic asthma and bronchial asthma and encompasses a large number of more or less specific, more or less definable designations (Table). These dictionary terms are all "asthma," with a word of conjecture about the cause. These modifying words suggest scientific precision but add little to our understanding that the patient is breathing with difficulty and a wheeze except that his problem occurs in the summer, near a horse, or somewhere else. These modifying words do not suggest that the patient's asthma can be caused by mucus, edema, foreign body, infection, as well as spasm. Moreover, this list of kinds of asthma ignores the fact that asthma may be the initial or major symptom in almost every disease of the upper and lower respiratory tracts.

The clinician fares poorly when he tries to use bronchitis as a diagnosis. Bad as the term asthma is, it describes a symptom seen or heard by the clinician. Bronchitis is worse, for the supposedly inflamed bronchi are never seen, heard, or touched during a clinical examination. Use of bronchitis as a diagnostic term is, therefore, purely inferential unless a bronchoscopy is done. Perhaps "bronchitis" should be left to the pathologist who can see and touch and microscopically evaluate the bronchial tree at autopsy.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

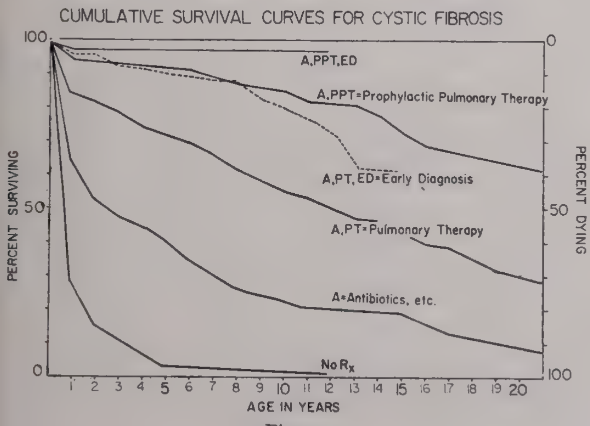
†Department of Pediatrics, University of Minnesota Medical School.

The term "chronic bronchitis" has been subjected to some restrictions by internists. These restrictions, which apply to adult medicine, give diagnostic import to bronchitis as a clinical symptom: "Chronic bronchitis refers to the condition of subjects with chronic or recurrent excessive mucous secretion in the bronchial tree." Since the pediatrician does not use this restricted definition of chronic bronchitis, he probably means only that the patient has had a chesty cough for a long time.

In an adult or child, when either clinical symptom is used for a diagnostic term, the morphologic, physiologic, etiologic, and prognostic aspects of precise diagnosis are overlooked.

Since the terms used for diagnosis provide the loci for treatment or prevention and for prognosis, the clinician who defines the topographic, morphologic, physiologic, and etiologic aspects of the patient's illness and retreats to the diagnosis, asthma or bronchitis, is in trouble. The specifics of diagnosis that are omitted by these words and the diversity of specific diseases that fall under their broad umbrellas should convince us that "asthma" and "bronchitis" do not constitute scientific diagnosis and should make us appreciate that their use as diagnostic terms has led to many disagreements concerning methods of evaluation and treatment.

The chest physician can commit no greater crime against scientific medicine than to continue to use "asthma" and "bronchitis," as Hippocrates did, to designate diseases. Many of Hippocrates' diagnoses, for example, fever and cyanosis, have been retired as diseases and are recognized to be signs or symptoms of diverse diseases. Perhaps it is time for asthma and bronchitis to surrender their claims to be diseases and to accept recognition as disease manifestations. Hence, in this article, the term "asthma" will mean labored breathing with wheezing and the term "chronic bronchitis" will mean a cough persistent for three or more months with or without production of sputum.



Figure

Cystic Fibrosis

The clinician fares better with the "classic" 30-year-old cluster of symptoms that was called cystic fibrosis of the pancreas and is now generally called just cystic fibrosis. When a child presents with failure to thrive, a ravenous appetite, a distended abdomen, wasted extremities, chronic cough with or without sputum, clubbed fingers, barrel chest, with or without signs of cirrhosis of the liver or vitamin A deficiency, few clinicians will make any other clinical diagnosis. But our modern definition also regards cystic fibrosis as the unknown metabolic defect that leads to these clinical manifestations. Therefore the clinician must now make this diagnosis in children who have only a positive sweat test with all variations of the classic symptoms from minimal to maximal. Many of these children have symptoms of asthma or of bronchitis and would without a sweat test have been given that clinical diagnosis.

The frequent dissociation of these classic clinical manifestations of cystic fibrosis from the laboratory tests that are closer to the basic genetic defect is the reason that many physicians recommend that the diagnosis of cystic fibrosis never be made in the absence of a positive sweat test and that the sweat test be done whenever a child presents with any of the classic symptoms. Cystic fibrosis has frequently been confused with asthma and chronic bronchitis because these terms are symptoms, not diseases, and because any child with cystic fibrosis can present with asthma or with bronchitis.

Since cystic fibrosis is a genetic disease identifiable by increased salinity of the sweat, the reasons why many physicians do not order a sweat test on every child with asthma or chronic bronchitis need to be studied. Most physicians consider the possibility of cystic fibrosis in these children, but reject the need for a sweat test because of one or more misassumptions concerning the disease.

False Assumptions

The following misassumptions were found in the histories of children discovered to have cystic fibrosis during the past eight years. These assumptions are misleading doctors every day; they are not strawmen.

The most common reason for an incomplete diagnostic work-up is the assumption that the child who looks well cannot have cystic fibrosis. However, all physicians caring for even moderate numbers of patients with cystic fibrosis can demonstrate patient after patient whose height and weight are average or above average and who look *too well* to have cystic fibrosis. These physicians can also demonstrate children in whom the diagnosis was made when they were *too well* to have cystic fibrosis, because a thorough physician ordered a sweat test on the basis of symptoms of asthma or chronic bronchitis.

The second false assumption is that the patient is too old to have cystic fibrosis. Our knowledge of the natural history of untreated cystic fibrosis suggests an extremely high mortality in the first few years of life (Curve Rx) so that it is therefore possible to predict that few if any patients alive today with cystic fibrosis were born prior to the development of sulfa drugs in 1939. Thus the assumption is correct that a patient over 40 years of age is too old to have cystic fibrosis.

On the other hand, all patients under forty years of age are likely to have been treated with antibiotic or chemotherapeutic agents for acute infections, and for patients with cystic fibrosis receiving such therapy the outlook is much better (Curve A). In the experience with this group of patients at the University of Minnesota, the longest interval from birth to diagnosis was 19 years in the case of a young lady who had a constant cough for 14 years and proven bronchiectasis for seven years.

Almost every Cystic Fibrosis Center has patients in the twenties, some have patients in the thirties, and some have female patients who have become pregnant and have delivered children. Therefore, if a patient has asthma or chronic bronchitis and has never had a sweat test, it would be sheer medical folly to perpetuate an incorrect diagnosis by failing to do a sweat test because the patient was in his late teens or twenties.

The third assumption is that the patient must have steatorrhea. This is based on ignorance of the fact that one of five young children with cystic fibrosis has no demonstrable pancreatic insufficiency. Furthermore, steatorrhea may not be clinically obvious, for a child with pancreatic insufficiency may restrict his fat intake and so decrease his steatorrhea. Moreover, the patient who develops pancreatic insufficiency at an older age has a relatively greater absorptive capacity of his small bowel, a decreased basal requirement for energy and a decreased requirement for growth.

The fourth assumption is that it doesn't make any difference whether or not you make the diagnosis of cystic fibrosis; the child is going to die anyway. Although the increased longevity associated with antimicrobial therapies is sufficient evidence to cast doubt on this proposition, the even greater longevity with more intensive pulmonary therapy refutes this negative view. When children with cystic fibrosis are given postural drainage, aerosol and mist-tent therapy in addition to antibiotics, a dramatic improvement in survival is observed (Curve A, PT). Furthermore, when this more intensive therapy is used continually from the time of diagnosis, the mortality is even more significantly reduced (Curve A,

PPT). The conclusion is obvious that diagnosis of cystic fibrosis is important, for intensive treatment can effect a seven-fold increase in the number of survivors to age 20 years.

The fifth similar assumption, often used as an excuse to defer diagnosis, is that there is no need to hurry to make the diagnosis because treatment can be delayed and still be effective. This assumption is based on the frequent observation that the younger the child is at the time of symptoms leading to diagnosis, the more severe the course and complications.

Data from two large Cystic Fibrosis Centers show further improvement in survival when early diagnosis is coupled with initiation of therapy. The survival Curve A, PT, ED is to be compared with therapy delayed until the onset of symptoms (Curve A, PT), and the other Curve A, PPT, ED is to be compared with Curve A, PPT. Thus the benefits of therapy are greater when given early in the course of the disease.

The sixth assumption, that cystic fibrosis is a rare disease, has given some false comfort to the physician who doesn't do sweat tests. However, cystic fibrosis is not rare. It is the most common, fatal if untreated, genetic disease. It is transmitted by an autosomal recessive gene which is found in 5 to 6 percent of the population. It occurs in one of every 1000 to 1600 newborn infants. It is ten times more common than that in children with symptoms of asthma or bronchitis. The pediatrician who is a consultant in allergy or chest diseases and who sees five new patients a week should expect to see two patients with cystic fibrosis every year.

The seventh assumption is that sweat tests are a waste of the patient's family's money. This provides comfort only to the physician who has not analyzed the costs. Since the child with asthma or bronchitis may very likely be given an allergic workup, even started on an allergic treatment program, these costs must be considered. The cost of a sweat test is insignificant when compared to the cost of allergic treatment and to the fact that the cost of failure to provide intensive pulmonary care to the child with cystic fibrosis is progressive pulmonary destruction and early death. The money saved by not testing the 120 other children who did not have cystic fibrosis will probably be spent annually by the family of the cystic fibrosis child who had delayed treatment because the cost of treatment of a damaged lung is that much greater than the cost of prophylactic pulmonary therapy for an undamaged lung.

The eighth assumption is that every child with cystic fibrosis has a cough. Careful reading of case histories or of reports of series of cases clearly reveals that some children with cystic fibrosis have other presenting symptoms, such as steatorrhea, cirrhosis, failure to gain weight, edema, hemorrhage, heat prostration, bowel obstruction, or prolapse of the rectum.

The ninth assumption is that all sweat tests are equally good. However, authorities on cystic fibrosis agree that no screening test can be relied upon to differentiate disease from normality in a suspected patient. Clinical judgement must overrule the test if negative, since false negatives do occur and clinical judgement must seek affirmation in a quantitative sweat test if the screening test was positive, for false-positive tests also occur. Furthermore, since technologic variations can alter the range of normal values and the range of pathologic values in the sweat test, as in any laboratory test, every laboratory should establish its own ranges to aid the clinician in interpretation of sweat test results.

The tenth misleading assumption is that one sweat test is sufficient. Perhaps no false assumption is as cruel as this one, for it can lead to false-positive and false-negative diagnosis. When the clinical suspicion of cystic fibrosis exists, quantitative sweat tests should be done in *duplicate* or *triplicate*. The analytical procedures in all hospital laboratories have far greater precision than is required to make this diagnosis, for the range of typical normal values is vastly different from the range for values diagnostic of cystic fibrosis. Despite the accuracy of these instruments, on occasion a great variation may be observed in the salt content in sweat tests done simultaneously on the same individual. The error is rarely in the analytical technique, but is usually in the collection technique where a great many places for error exist. The magnitude of these errors and their random accumulation can be sufficiently great in both the positive and the negative direction to cause a single sweat test to give falsely high or falsely low values for the true salt content of the patient's sweat. The only safety for the clinician is to replicate the collection technique once or twice to reduce the chance of error to something that is clinically acceptable. When two or three sweat tests are done on a patient suspected of having cystic fibrosis and the results are comparable and in agreement as to the presence or absence of the disease, the clinician is secure in declaring the child to have or not to have cystic fibrosis.

Conclusions

The terms asthma and chronic bronchitis are inadequate for precise diagnosis of disease. Asthma should be restricted to the description of "difficult breathing with wheezing" and chronic bronchitis to a "persistent cough with or without sputum production."

Cystic fibrosis is a generalized metabolic disease in which asthma or bronchitis is the frequent first symptom.

Cystic fibrosis can be specifically differentiated from other causes of asthma and bronchitis by the sweat test. The careful clinician will have duplicate sweat tests done on every patient referred with symptoms of asthma or bronchitis.

Are Doctors Human?

The truth is that doctors *are* human; that they seem otherwise at times is purely the fault of us patients. Doctors know our deepest secrets not by some demoniac process of mental telepathy but because we insist on trotting the secrets out. We do this ostensibly to aid in treatment, actually to ease our guilty consciences or to show what rips we are or maybe just to keep the old tongue wagging.

Doctors are pampered, certainly, and yet how many of them go out of their way to attract an excess of esteem? Generally it comes to them against their will and for reasons so transparent that a two-year-old could see through them. So-and-So butters Dr. Smith to the skies at Mrs. Jones' bridge party, hoping to get a bit of free medical advice later on in the evening. Mr. Brown is also there buttering away at a great rate.

Closely connected with the pampering is the tendency to envelop doctors in an aura of infallibility. . . . Few doctors relish this role of infallibility. They know perfectly well that the real workers of miracles are the patients themselves, nine out of ten of whom meet the test of illness with astonishing heroism, persistence, patience, and self-discipline. Doctors set the stage by surgery or medicine or advice. The patient has to put the show over.

Every one of my sixteen docs has been ready and eager to admit that he is as apt to pull bloopers as any professional man or craft worker. The surgeon who yanked out my appendix frankly informed me next day that the appendix was not my trouble and that he was darned if he could find anybody who could tell him what *was* my trouble. Six months later I went through a diagnostician's clinic, garbed in a sheet like Gandhi and drinking gallons of barium. After two days of this, the head diagnostician announced his findings. "All I can discover," he said sheepishly, "is that you're allergic to turnips. To be honest with you, that doesn't mean a thing. Practically everybody I ever put through the clinic is allergic to turnips."

My present doctor has a favorite yarn about a convalescent in our hospital who hadn't seen his doctor in two years. When the doctor finally turned up, he said to the anxious convalescent, "Are you still here? Why, I meant to tell you two years back to get up and go home!"*

Today, more and more medical clinics —even two and three-doctor groups— are becoming incorporated so they can benefit from the income-tax savings that are possible when corporate profit-sharing trust funds are established.

And many of these groups are currently making use of our comprehensive investment management service that features continuous supervision of profit-sharing funds. In addition, we provide full administrative services, including: monthly statements of trust, annual reports for participants, preparation of tax forms, and custody of securities.

For more information, just fill out the attached postage-paid card and drop it in the mail.

Inhalation Therapy*

for Chronic Obstructive Pulmonary Disease

LeROY W. MATTHEWS, M.D.†
CARL F. DOERSHUK, M.D.†
Cleveland, Ohio

INHALATION THERAPY has been used empirically for many years in the treatment of chronic obstructive pulmonary disease,[1-4] but considerable disagreement still exists on the safety and efficacy of such measures as oxygen and humidity control, heated nebulizer inhalations, intermittent positive pressure breathing, mist-tent therapy and aerosol medications. Most investigators who have carried out careful studies agree on the value of these measures; but there can be little doubt that effective utilization requires an understanding of the basic physical principles involved, as well as knowledge of the pathology and pathophysiology of the disease under treatment and of the potentially harmful effects of each measure.

General Considerations and Principles

The objectives of inhalation therapy include improved and more even ventilation of the lungs, increased oxygenation of the arterial blood, more effective elimination of carbon dioxide, the wetting and thinning of bronchial mucous secretions and the deposition of locally effective medications (decongestants, bronchodilators, anti-inflammatory and mucolytic agents, and antibiotics) directly on the mucous membranes of the tracheobronchial tree.

Most of the diseases that cause obstruction of the bronchial tree do so by producing excessive or abnormally viscous secretions or a combination of these, bronchospasm, inflammation and edema of the mucous membranes, and eventually destruction and fibrosis.

Treatment

Effective treatment, in general, must be initiated before significant destruction and fibrosis have occurred and is aimed primarily at the removal of secretions, relief of bronchospasm and elimination of inflammation, edema and infection in the mucous membranes.

Nebulization

Nebulization therapy is an extremely valuable and effective therapeutic measure which is used to wet and thin bronchial secretions and to deposit locally effective medications in the respiratory tract. It should not be confused with humidification.

Composition of Mist

The site of deposition is largely dependent on particle size of the water mist which is produced by the nebulizer, by the composition and vapor tension of the solution nebulized, and by the humidity of the air used to produce nebulization and to carry the aerosol to the respiratory tract. In general, large particles over 10 microns in diameter are deposited by inertial impaction in the upper airways,[5] and rarely penetrate beyond the nose with nasal breathing or beyond the larynx with mouth breathing. As particle mass decreases, sedimentation becomes the primary mechanism. The smaller the particles the farther they are carried in the bronchial airstream. Only particles smaller than 1-2 microns in diameter reach the bronchioles. Brownian motion, the primary mechanism for deposition of particles under 0.5 microns, is relatively unimportant in nebulization therapy.

In general, disease in the upper respiratory tract and larynx is most effectively treated with water or saline particles ranging from 5 to 10 microns in diameter. Small infants with laryngotracheal disease will often breathe through the nose and remove almost all particulate water over 6 microns in diameter before it reaches the larynx and upper trachea.[6] To treat upper airway disease a nebulizer, a high humidity room or a mist tent that produces particles with a mean particle size of 5 microns will be most effective. However, nebulizers producing particles 5 microns or more in diameter are of little value in treating disease in the periphery of the bronchial tree. To effectively treat the pulmonary lesion of cystic fibrosis, bronchitis, asthma, or bronchiolitis where involvement begins in the smaller bronchioles and extends toward the bronchi, nebulizers that produce particles in the 1-5 micron diameter range should be used, and the particle size should be stabilized by either heating and humidifying the carrier air or by reducing the vapor tension of the nebulized solution by adding propylene glycol.

Jet-Type Nebulizers

Jet-type nebulizers which produce this particle size are unsatisfactory because the aerosol produced by them contains less water (30 microliters/liter of air) than it takes to produce 100% humidity in the inspired air (44 microliters/liter) as it is warmed to 37°C in the respiratory tract.

Ultrasonic Nebulizers

Ultrasonic nebulizers are now available which produce dense aerosols (45-67 microliters/liter of air) of small and more uniform particle size. When used for mist-tent therapy these units produce a mist in the tent which contains enough water to adequately provide for humidification with a significant amount left as particulate water for deposition in the periphery of the lung. With such nebulizers distilled water can be nebulized, but inhalation of such a mist produces a cough and evidence of nasal and bronchial irritation in many patients. Normal pulmonary secretions are isotonic. When normal saline is nebulized no immediate irritation is noted, but over a period of time (weeks) it becomes apparent. This is thought to be the result of evaporation from the mist-particle which results in the deposition of salt particles is quite hypertonic. Use of ½ strength saline or 5% propylene glycol results in the deposition of a relatively isotonic solution and eliminates all evidence of irritation in most patients. A few asthmatic patients are encountered who develop bronchospasm after inhalation of any particulate material. For them nebulization therapy is contraindicated.

In utilizing nebulization therapy the density of the aerosol or mist produced, to be effective in wetting and thinning secretions, must be so dense that it is difficult to see the patient in the tent. Breathing with a rapid inspiratory flow and breathing through the nose will both increase upper airway deposition, while deep slow breathing through a wide open mouth will markedly increase deposition in the peripheral airways.

Nebulization therapy can be divided into two types: (1) Mist-tent therapy and direct inhalations from heated jet or ultrasonic nebulizers which are used over prolonged periods to add water to the pulmonary secretions, and (2)

Medication aerosol therapy which is used to administer topical medication over brief periods intermittently during the day.

Mist-Tent Therapy

Temperature and Humidity

In the hospital and most patient's homes during the respiratory disease season the temperature averages 22°C and the relative humidity less than 50% (10 microliters of water/liter of air). When air at this temperature and humidity is used to produce nebulization or to carry the mist into a tent, it quickly becomes 100% saturated with water vapor (20 microliters of water/liter of air) by evaporation of the nebulized water. Evaporation then continues to occur in the tent to replace the water vapor constantly diffusing out of the tent. A plastic tent and a cooling unit or room air-conditioner are needed regardless of the nebulizer used. The human body will increase the temperature in the tent above room temperature; also the loss of body heat by evaporation is markedly decreased in a saturated environment. Cooling the tent to 70°F or reducing the room temperature to 62-65°F will usually permit adequate heat loss by radiation and conduction.

Propylene Glycol

Because the vapor pressure of small droplets is increased by the curvature of their surface they tend to evaporate more rapidly and may be completely eliminated if plain water is nebulized. When the deposition of a larger volume of water in the peripheral bronchial tree is desired, an ultrasonic nebulizer should be used. When a smaller volume appears to be sufficient, the jet-type nebulizers may be adequate if a solution of 10% propylene glycol or 1% saline is nebulized. In any case, the nebulizer used should produce particles ranging in size from 1-5 microns in diameter.

Mist tents in general should be operated with compressed air utilizing oil-less compressors. The use of oxygen may result in oxygen concentrations in the tent which are capable of impairing the ciliary clearance mechanism of the tracheobronchial tree.[7]

Duration of Use

In treating patients with chronic obstructive pulmonary disease the mist tent can be used prophylactically as well as therapeutically. During acute flare-ups of such diseases, the patient should be kept in the tent from 10 to 18 hours/day. Continuous therapy should be avoided because it may have deleterious psychologic effects or lead to fungal infections or maceration of the skin. When such therapy is used prophylactically to prevent development or progression of chronic pulmonary disease, it is used only during sleeping hours. All of our cystic fibrosis patients and many of our patients with chronic bronchitis, bronchiectasis and asthmatic bronchitis sleep in mist tents every night at home.

Evaluation of Mist-Tent Therapy

Pulmonary Function Test Evaluation of Mist Tent Therapy and Propylene Glycol

In the initial evaluation[8] 20 patients were started on a complete therapeutic program except for omission of the mist tent. Pulmonary function studies were obtained at three-month intervals for three consecutive periods. At the end of this nine-month control period, mist-tent therapy, utilizing 2 MG II C Mist-O_2-Gen nebulizers to nebulize 10% propylene glycol in distilled water, was added to the treatment program. Repeat pulmonary function studies were performed two months later and then at four-to-five-month intervals over the next year. During the three periods before introduction of the mist tent some random variation occurred, but the changes cancelled each other and no significant changes were observed. In contrast, when the mist tent was added, significant changes in the direction of improvement were observed for all of the parameters measured except for vital capacity. The study patients had relatively mild disease with only small deficits in vital capacity; so lack of improvement in this parameter was not surprising. The changes seen in functional residual capacity, residual volume, the ratio of residual volume to total lung capacity and in maximum breathing capacity were all significant at the 0.005 level of probability. This improvement was then maintained with continued use of the mist tent and no significant changes were observed over a one-year followup period.

Tests Omitting the Mist Tent

A similar study[8] was carried out on 16 patients who were placed on the entire therapeutic program including mist-tent therapy. After their condition stabilized, as shown by pulmonary function tests over three consecutive control periods, the mist tent was eliminated from the treatment program for one month. This resulted in significant changes in the pulmonary function parameters in the direction of increased airway obstruction and over-inflation. The patients were then returned to their mist tents. Pulmonary function tests two months later and over two subsequent control intervals revealed quantitative reversal of the changes.

Evaluation of Ultrasonic Nebulization of Saline

A similar study[9] has been completed aimed at determining whether mist-tent therapy utilizing a DeVilbiss ultrasonic nebulizer using normal saline is superior to conventional mist-tent therapy utilizing jet-type nebulizers and 10% propylene glycol in sterile distilled water. For this study 41 patients were selected who had persistently abnormal pulmonary function tests despite intensive, continuous home therapy including the use of a jet-type mist tent. All of the patients were in relatively stable control as shown by pulmonary function tests obtained at three-month intervals for at least six months before the study was initiated. The only changes made were substitution of the ultrasonic nebulizer for a one-month period for the two jet-type nebulizers normally used, and a change from 10% propylene glycol in distilled water to normal saline as the nebulized solution.

The experimental design in this study was similar to that described above. All of the patients had advanced pulmonary involvement; so a tendency toward progression was seen in the mean differences for vital capacity and maximum breathing capacity during the second control interval. In contrast, after one month of therapy with the ultrasonic nebulizer, marked changes, all in the direction of improvement and all statistically significant at the 0.001 level of probability, were seen for all the parameters measured. Quantitative reversal of these changes was then observed in tests performed one month after return to the jet-type mist tent.

Saline vs Propylene Glycol

Since it was possible that the presence of salt or the absence of propylene glycol in the solutions nebulized in the ultrasonic tents contributed to the results obtained, 12 patients whose pulmonary function tests were stable on long-term ultrasonic mist-tent therapy were changed from 0.45 gm.% NaCl to 5% propylene glycol as the nebulized solution for a one-month period. This resulted if anything in slight further improvement.

Medication Aerosol Therapy

The chief purpose of intermittent aerosol therapy is the administration of potent medications in relatively small quantity. To shrink back edema of the bronchial mucosa, 1/8% phenylephrine can be nebulized. To relieve bronchospasm, a 1:200 solution of isoproterenol is effective. To decrease the growth of bacteria in the pulmonary secretions, antibiotics can be administered. To diminish the inflammatory reaction in the mucous membranes, steroids can be used. Theoretically it should also be possible to liquefy secretions by administering enzymes such as Dornovac or mucolytic agents such as N-acetylcysteine or urea; however, we have never been able to document such effects objectively.

MistO$_2$Gette or Bennett Twin Jet

We have found small nebulizers like the ETIF MistO$_2$Gette or the Bennett Twin Jet nebulizers to be safest and most effective for this form of therapy. The units can be used with either a plastic mouthpiece or a small face mask. Instruction of the patient in the techniques of breathing and the use of a mouthpiece undoubtedly lead to more effective therapy by avoiding impaction of the aerosol in the nose; but small infants and uncooperative older children can be effectively treated with a face mask. These nebulizers should be operated with the same type of compressor used for jet-type mist-tent therapy. Because of their size and requirements for a compressor and a source of electricity they cannot be carried in the child's pocket. This is a distinct advantage because it greatly decreases the probability of over-usage and dangerous toxicity.

Intermittent Positive Pressure Breathing Apparatus

In selected patients with asthma, an intermittent positive pressure breathing apparatus can be used to administer the aerosol more effectively; however, such therapy may be more harmful than beneficial in patients with cystic fibrosis who, in general, do not show a dramatic response to drugs such as isoproterenol. Because a pulmonary function test evaluation of intermittent positive pressure breathing therapy in children with cystic fibrosis revealed a progressive and eventually irreversible decrease in vital capacity and increase in air-trapping, we now use it only in the hospital for periods of less than two weeks and only on patients old enough to permit serial pulmonary function test evaluation of its effects.

Optimum Benefit from Drugs

In general, medication aerosol therapy is aimed at optimum absorption of the more potent sympathomimetic agents as well as local deposition of the decongestant, anti-inflammatory and antibiotic agents. Sympathomimetic bronchodilators are potent enough to produce a topical effect in the miniscule amounts carried by droplets less than 1 micron in diameter without producing much systemic effect. Because these droplets do not reach severely obstructed and poorly ventilated areas of the lung, the presence of some larger droplets that deposit in the larger bronchi from which the drug is absorbed to produce systemic effects is also beneficial. As the systemic effect opens the respiratory tract, more effective and even peripheral deposition of the constituents of the aerosol is achieved.

The Basic Solution

The constituents of an aerosol solution should be chosen to suit the individual patient's needs. We use a basic solution consisting of 1 part USP propylene glycol and 9 parts 1/8% phenylephrine. If significant bronchospasm exists, 0.1 to 0.5 ml. of 1:200 isoproterenol solution is added to 2 ml. of the basic solution. In patients with cystic fibrosis isoproterenol rarely produces a significant decrease in airway obstruction. When indicated, antibiotics such as methicillin (250 mg./ml.), neomycin (50 mg./ml.), polymyxin (4 mg./ml.), colistin (25 mg./ml.), carbenicillin (250 mg./ml.) and gentamycin (20 mg./ml.) are incorporated in the basic solution just before administration.

To avoid toxic effect the total dose administered over a 24-hour period should not exceed the recommended weight-calculated systemic dose. Aerosol administration of neomycin has been associated with hearing loss, especially in small infants and children under five years of age. The more potent steroids can also be administered by the aerosol route. Very small doses may produce significant pulmonary effects with minimal systemic effect; however, the systemic absorption of such drugs is readily demonstrated by the systemic effects produced by larger doses.

Aerosols of water or saline to wet and thin bronchial secretions can also be administered by direct inhalations from the nebulizer. Many older individuals who are uncomfortable or feel confined by mist-tent therapy will accept direct inhalations from either a heated, jet-type nebulizer or an ultrasonic unit. To be effective such inhalations must be continued over prolonged periods (approximately one hour) four times per day.

Precautions

All of the medications recommended above for aerosol administration are potentially harmful. Therefore, all should be prescribed carefully and their effectiveness evaluated in the individual patient clinically and, where possible, with before-and-after pulmonary function testing. Very potent drugs such as isoproterenol and potentially irritating medications such as protolytic enzymes, DNAase, N-acetylcysteine and urea should be avoided if they produce no significant beneficial effects.

Oxygen Therapy

Oxygen therapy should also be included in any discussion of inhalation therapy. One of the earliest manifestations of obstructive pulmonary disease is hypoxemia. This and the eventually associated respiratory acidosis cause an increase in pulmonary vascular resistance which eventually leads to cor pulmonale. Hypoxemia is primarily a result of uneven ventilation and abnormal ventilation-perfusion relationships in contrast to the hypercarbia and respiratory acidosis which appears only when total ventilation becomes insufficient. Increasing the O_2 content of inspired air will decrease the hypoxemia and often decrease pulmonary vascular resistance; but great care must be taken to be certain it does not result in decreased total ventilation with a resulting increase in PCO_2 and respiratory acidosis which then becomes the primary cause of increased pulmonary vascular resistance. In patients with severe chronic obstructive pulmonary disease, chronic exposure to a high PCO_2 may result in the respiratory center becoming insensitive to CO_2 and responsive only to hypoxia. In such patients the administration of O_2 eliminates the hypoxic stimulus and results in either cessation of respiration or such respiratory depression that the resulting CO_2 accumulation, narcosis and respiratory acidosis defeat all the purposes for which the oxygen was given.

Dangers

Even in patients with less severe pulmonary involvement, oxygen, especially at high partial pressures (over 450 mm.Hg.), is potentially harmful.[10] These harmful effects include a predisposition to the development of atelectasis, vascular congestion of the lungs, the appearance of an alveolar proteinaceous exudate and intra-alveolar hemorrhage, and eventual development of fibrosis. A recent study by Laurenzi et al.[7] also indicates that exposure of the respiratory tract to both low and high oxygen tensions has an adverse effect on the mucociliary clearing mechanism. This effect was observed at O_2 concentrations ranging from 25% to 100%, but in particular they caution against the administration of 100% oxygen to the hypoxic patient, since in their studies the sequential exposure of the respiratory tract to 10% and then 100% oxygen resulted in a more marked reduction in mucus flow than prolonged exposure to either concentration. It is interesting that in their studies the use of epinephrine, norepinephrine and isoproterenol by aerosol prevented or reversed this effect.

Conclusions

These studies confirmed our clinical observations and provide the first objective evidence of the value of mist-tent therapy in treating obstructive airway disease. The superiority of the ultrasonic over the jet-type nebulizer, at least for the short-term treatment of patients with advanced pulmonary disease due to cystic fibrosis, is clearly demonstrated. This is probably the result of increased deposition of water in the peripheral bronchial tree; but since the exact mechanism of action of mist-tent therapy has not been clearly elucidated, this remains conjecture.

In general, it is probably safer to administer inhalation therapy with compressed air and to utilize supplemental oxygen only when it is indicated. In most cases the benefits of supplemental oxygen can be obtained if the oxygen concentration is limited to 40% or a partial pressure below 300 mm. Hg. In all patients and especially in those with chronic respiratory insufficiency it is wise to raise the O_2 content of inspired air slowly while simultaneously monitoring its effect on respiration and on arterial PO_2, PCO_2 and pH.

Obstructive Lung Disease*

Treatment by Physical Therapy

DANIEL HALPERN, M.D.†
Minneapolis, Minnesota

THE IDEAL TREATMENT of bronchial obstruction would be the physical removal of the obstruction; however, it is not always possible or practicable to extract bronchial contents directly. Procedures have been developed, therefore, which can assist in the mobilization of intrabronchial material such as bronchial mucus and other secretions.

Initial efforts utilized mainly the principle of gravity whereby the patient was placed in one or more positions to allow drainage of individual bronchial segments.[1] By studying the anatomical disposition of the bronchial tree,[3] a series of positions were developed by which any one of the bronchial segments could be drained by placing the patient in a specific position.

At the Brompton Hospital in London, England,[2] the drainage posture was supplemented by various forms of manual vibration of the chest. As a result, there has evolved a technique of drainage combining positioning of the patient in a series of 13 positions, each related to a specific pulmonary segment together with the application of vigorous clapping alternating with manual vibration-compression applied over the area which is being drained in each individual position.[4]

Experience with cystic fibrosis has shown that a consistent form of bronchial drainage in conjunction with other measures such as vitamins, antibiotics, aerosol mist and digestive enzymes decreased the severity of pulmonary involvement in children. Doershuk and coworkers[5] reviewed a five-year multifaceted program and have shown improvement in 82% of patients treated, and in the first five years of life a decline in mortality to 3% from estimates for a similar group of untreated patients as high as 15%.

Manual Vibration-Compression

Vibration compression is done by placing the

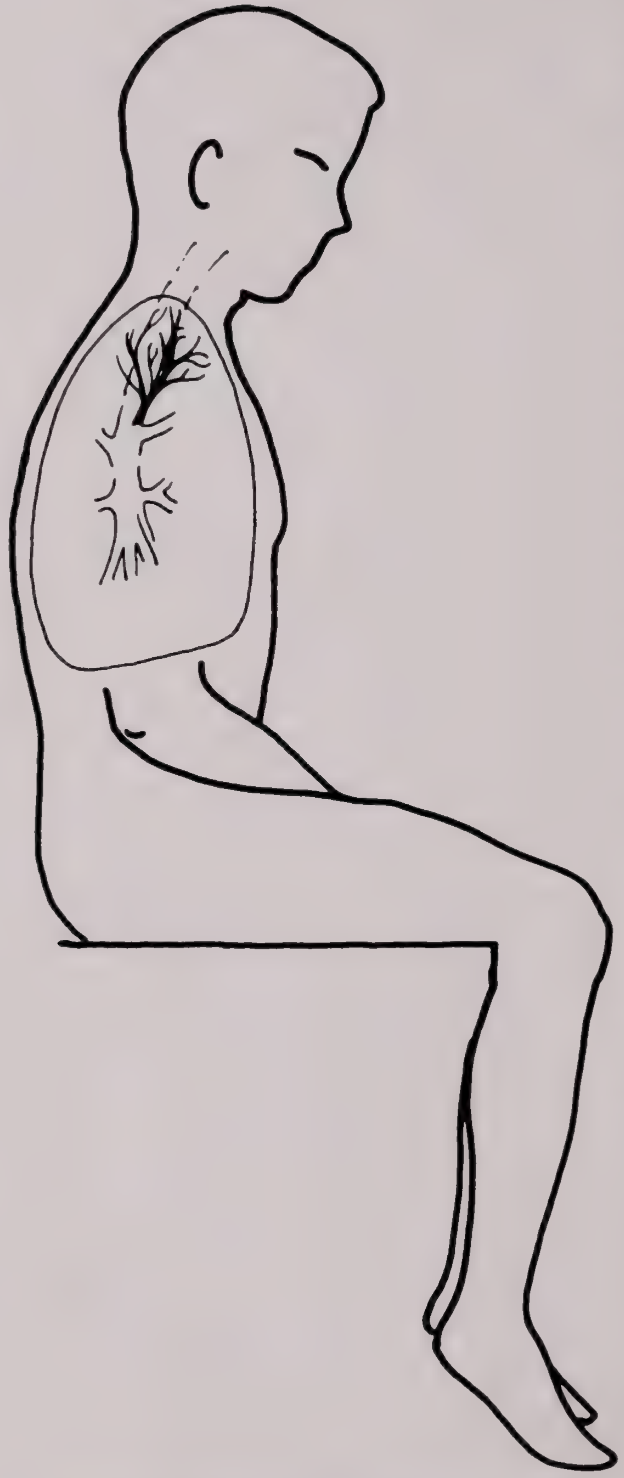

Fig. 1—Position relating to the apical bronchus, of the right upper lobe.

hands over the area of the chest to be treated, usually one hand on top of the other. For small children, using two or three fingers may be more appropriate for good localization. The hand in contact with the chest is curved to conform to the contours of the chest wall in order to obtain equal pressure throughout; isolated pressure with the finger tips or joints is usually uncomfortable and should be avoided. The vibration-compression is applied during expiration only. When the respiratory rate is rapid, the vibration should be applied every second or third breath. The hands are vibrated in a direction perpendicular to the skin surface, simultaneously with a compressive motion. The chest wall should move through an excursion of about a half inch in infants and small children to an inch or more in older children and adults. Pain or severe discomfort, over-fatigue, or interference with inspiratory efforts should be avoided. A rate of six to eight vibrations per second is generally satisfactory and appears to produce a cough effectively.

Clapping

Clapping the chest wall in the area overlying the lung segment to be treated is used alternately with vibration-compression; both hands are used and should conform to the chest contour. The chest may be protected by clothing or a towel to prevent skin irritation during the clapping, and enough force should be applied in clapping to move the chest wall. In this way, the clapping motion includes a terminal push to the chest rather than a single slap. As an alternate method, the hands may be held cupped and the cushion of air thus trapped provides protection against the pain of slapping.

The positions in which the patient is placed on the table are designed to place the segmental bronchi in as nearly vertical a position as possible. One or two pillows are used to stabilize the patient, with the table in (1) the horizontal, (2) the foot elevated 12″, (3) the foot elevated 18″ positions. At each elevation of the table the patient goes through a single rotation, stopping at the appropriate point for specific segmental treatment. Each position may be maintained three to five minutes as a rule.

Procedures With the Table Horizontal

Apical Bronchus of the Right Upper Lobe

The patient is instructed to sit upright on

All figures in this article previously published in Journal Lancet, 87:4, April 1967 by author.

the table with legs dangling (Figure 1). His back is supported by leaning against it or pressing with one hand while the other hand applies vibration compression to the infraclavicular area on the right side. He leans backward for a short period of time, then forward, then sideways to right and left during the treatment in order to drain the entire segment. Coughing is encouraged at all times, and if it begins during any part of the therapy, the procedure is interrupted and the patient's coughing assisted by supporting the lower costal and upper abdominal area with the hands.

Anterior Bronchi of the Right and Left Upper Lobes

Since the bronchi of these segments run almost directly anteroposteriorly, the patient lies on his back (Figure 2). A pillow may be placed under the knees and head for comfort. Vibration-compression and clapping may be carried out alternately over both right and left sides. Treatment is applied to the upper anterior portion of the chest at the level of the second and fourth ribs.

Posterior Bronchus of the Right Upper Lobe

From the supine position the patient turns toward the left side with the right side of the body turned forward to an angle of about 45° (Figure 3). Since the branches of this bronchus may extend in a craniad direction as well as a posterior, a slight elevation must be introduced to the chest in order to bring the inclination of the bronchus more closely to vertical. For this purpose a pillow is placed under the left axilla and left chest for support. Clapping and vibration-compression are applied to the upper posterior thorax in the general area of the lateral angle of the scapula.

Superior Bronchi of the Right and Left Lower Lobes

From the previous position a further turn of 45° brings the patient to the prone position. A pillow may be placed under the abdomen in order to flex the trunk slightly (Figure 4). Vibration-compression and clapping are applied to the back of the chest bilaterally at a level just above the lower angle of the scapula.

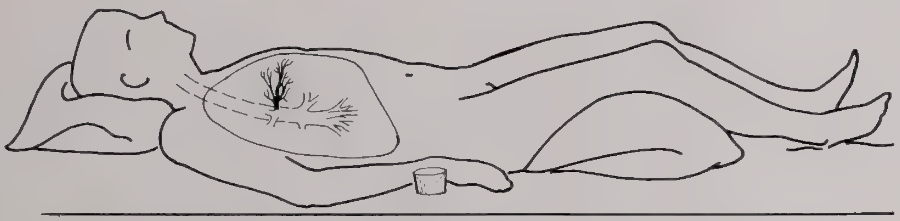

Fig. 2—Position relating to the anterior bronchi, of the right and left upper lobes with the table horizontal.

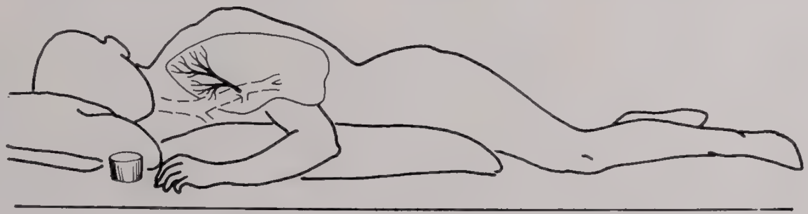

Fig. 3—Position relating to the apical posterior bronchus of the left upper lobe. The position for the posterior bronchus of the right upper lobe is a mirror image.

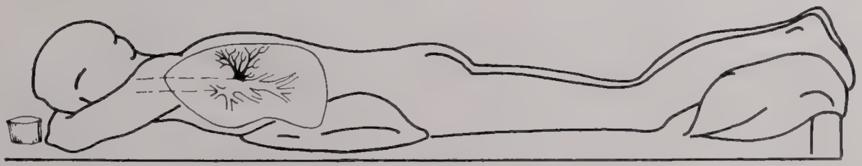

Fig. 4—Position relating to the superior bronchi of the right and left lower lobes.

Apical Posterior Bronchus of the Left Upper Lobe

Continuing the rotation by 45°, the patient now comes to lie on his right side with the left side of the body turned forward at an angle of 45°. A pillow is placed under the right axilla and right chest for support, bringing the bronchus into a vertical position. This position is a mirror image of that for the posterior bronchus of the right upper lobe (Figure 3). Treatment is applied to the corresponding area on the left side.

Procedures With Foot of Table Elevated 12 Inches

Lower Division, Left Upper Lobe (Lingular)

For the next two positions, the foot of the table is elevated 12″. The patient lies on his back, turned 45° toward the right. A pillow extending from the left shoulder to the left hip is placed along the back for support. Treatments are applied over the lateral anterior portion of the chest from the level of the third to the sixth rib.

Right Middle Lobe

Since the right middle lobe is the counterpart of the lower division of the left upper lobe, the bronchus runs in the same direction as the mirror image of the previous segment. The patient, therefore, lies on his back with his body turned toward the left side at an angle of about 45° (Figure 5). A pillow under the back extends from the right shoulder to the right hip for support. Vibration-compression and clapping are applied to the right antero-lateral portion of the chest from the third to the sixth rib.

Procedures With Foot of Table Elevated 18 Inches

The positions required to drain the segments of the lower lobes of the lungs are achieved by raising the foot of the table about 18″. Each segment is treated systematically by stopping at six different positions during a single rotation. One of the major bronchi of the lower lobes is thus placed in a vertical orientation during each of the six positions.

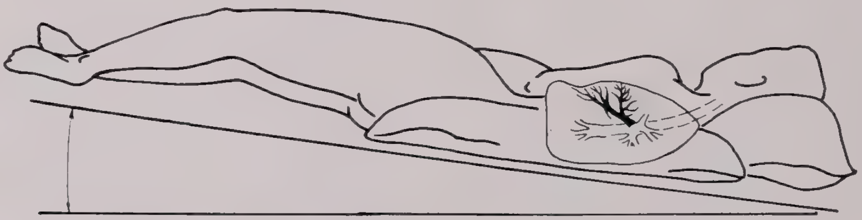

Fig. 5—Position with the foot of the table elevated 12 in., corresponding to the right middle lobe.

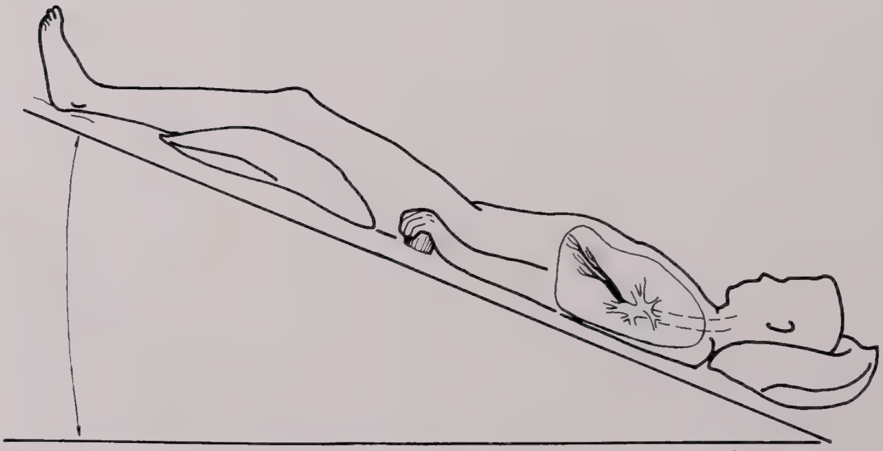

Fig. 6—With foot of the table elevated 18 in., position relates to medial basal bronchus of the right lower lobe.

Medial Basal Bronchus of the Right Lower Lobe

The patient starts in the supine position (Figure 6). Compression-vibration and clapping are applied over the lower portion of the right anterior rib cage.

Anterior Basal Bronchus of the Right Lower Lobe

The bronchus is slightly lateral to the medial bronchus. The patient turns halfway to the left, a pillow under the right side to support the back. The treatment is applied to the anterolateral aspect of the rib cage in approaching the anterior axillary line at a level between the seventh and 10th ribs.

Lateral Basal Bronchus of the Right Lower Lobe

The lateral basal segment is placed in the general area of the lateral aspect of the chest from about the sixth to the 10th rib. The patient lies directly on the left side with a pillow under the crest of the ilium to maintain the vertebral column in a straight line parallel to the table (Figure 7). The pillow should be carefully placed in order to insure proper positioning. If the pillow is placed too close to the trochanter, the lower chest will sag and the inferior portions of the basal bronchi will be inadequately oriented in the vertical direction. Treatment is applied to the right lower chest over the lateral surface.

Posterior Basal Bronchi of the Right and Left Lower Lobes

Vertical orientation of these segmental bronchi is obtained in the prone position with two pillows placed under the hips. With the elevation of the foot end of the table, the thoracic spine can be positioned at an angle of about 45° to the floor in this way. In some instances it is necessary to place a pillow and a board at the head or shoulder straps to prevent sliding

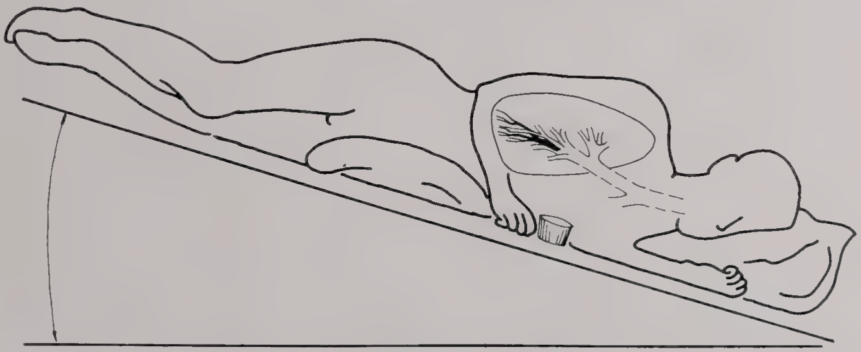

Fig. 7—With foot of table elevated 18 in., position relates to the lateral basal bronchus of the right lower lobe.

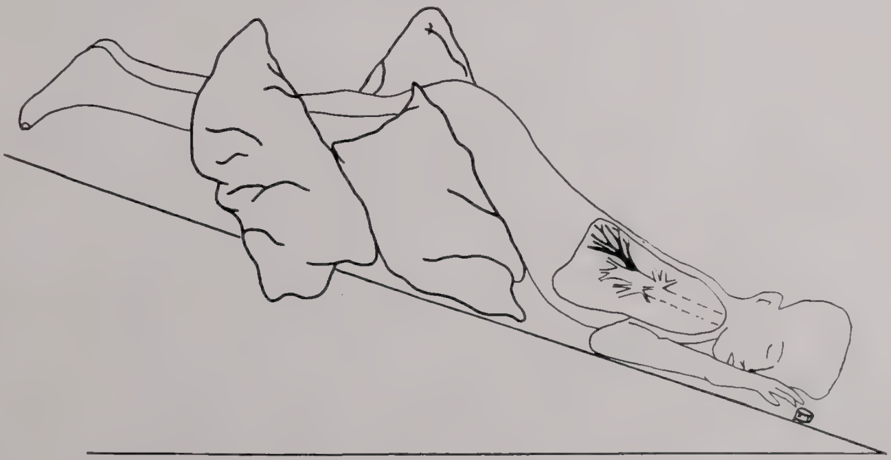

Fig. 8—With foot of the table raised 18 in., the position relates to the posterior basal bronchi of right and left lower lobes.

downward. If the legs are allowed to hang below the upper end of the table, this may also prevent sliding (Figure 8). Treatment is applied bilaterally to the lower chest posterior. This position can also be achieved in older children and adults by having the individual hang over the edge of the bed with arms on a chair or on the floor. This position will be recognized by many as that associated with the term "postural drainage" and has been in common use for treatment in adults with chronic bronchial disease such as bronchiectasis. However, since emphasis in this procedure is placed equally on the vibration-compression and clapping as well as on the positioning, the preferred term is "bronchial drainage."

Lateral Basal Bronchus of the Left Lower Lobe

This position is a mirror image of that required for the right lateral basal bronchus (Figure 7). The patient lies on the right side and a pillow is placed under the right lower ribs and ilium. Treatment is applied to the lower lateral area of the left rib cage.

Anterior Medial Basal Bronchus of the Left Lower Lobe

The patient lies on his back, with his body turned slightly to the right. A pillow along and underneath the back on the left will provide support and prevent rolling. Treatment is applied to the lower anterior portion of the left chest.

Discussion

A suitable tilting table for home use can be made of five or seven-thickness laminated plywood, hinged at one edge with a support which can be placed alternatively at two heights corresponding to the 12″ and 18″ elevation (Figure 9). Such a table may be padded and placed on the child's bed or kitchen table when in use, and can be folded conveniently out of the way during the rest of the day.

For a young infant the positions may be modified by using the lap. Tilting can be accomplished by crossing the legs and laying the

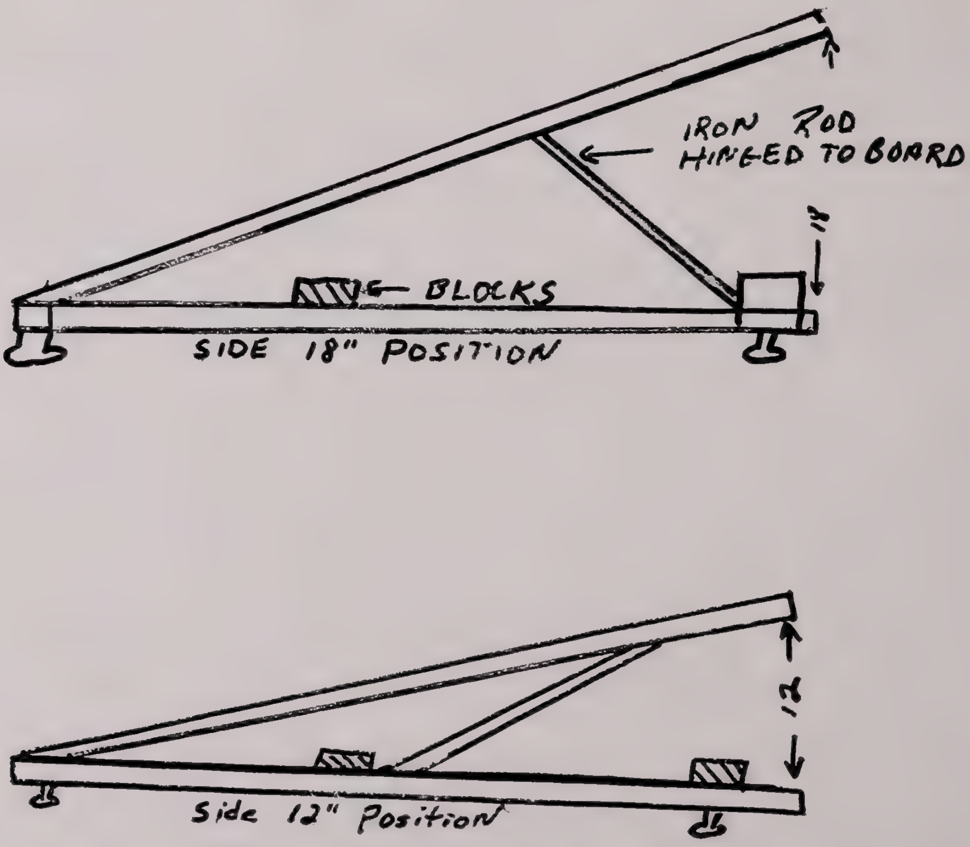

Fig. 9—Tilt board for bronchial drainage.

child across the lap in the appropriate direction or by placing one foot on a foot stool. When the baby is tilted downward, a firm grasp of the lower extremities by the elbow and forearm of the individual treating the child will prevent slipping. The feet of the child should not be against the abdomen of the adult treating, but should extend freely beyond the lap. When the respiratory rate in an infant or young child is rapid, it may be necessary to apply the compression-vibration during every second or third expiration. It is essential that no compression be applied during inspiration as this is fatiguing for the patient.

Each position should be maintained at least three to five minutes. The duration of treatment and the frequency of repetition to a particular area may be varied from two to four or more times daily depending on the degree of involvement and the rapidity of re-accumulation. When bronchial secretions are localized to a small area of one or two segments, treatment may be concentrated to these areas alone. If follow-up of a patient is close, the prescription may vary from time to time depending upon the degree and location of involvement. The complete procedure takes from 39 minutes to an hour. If this is to be carried out twice a day, there should be a distinct clinical indication, since most families will find this a serious burden if the treatment has to be carried out indefinitely. Most children with cystic fibrosis have fairly generalized involvement, and require persistent observation and treatment. When the chest is completely clear in such children, it may be useful to treat a number of selected areas on a prophylactic basis. The segments most frequently needing persistent treatment include the upper apical segments, right middle lobe, the right and left lateral basal and posterior basal segments. Treatments may be discontinued completely depending upon the rate of re-accumulation of intrabronchial mucus as observed over the period of time between examinations. Patients or their families should be instructed to resume treatment with onset of respiratory infections or spontaneous coughing.

The intensity of treatment should be limited by the clinical condition of the patient. For individuals with limited activity tolerance, dyspnea, or right heart enlargement, a full treatment program for one hour will often be exhausting, if not hazardous. The treatment should be observed and, if necessary, limited to one or two segments at a time, at intervals during the day. Treatment is best given in the morning, directly on arising, and immediately after inhalation of aerosol mist, preferably containing a mucolytic agent. In the evening, treatment is best given at least one hour after meals to avoid emesis.

The procedure of bronchial drainage has been shown to be effective in the maintenance of adequate bronchial hygiene in such chronic obstructive lung disease as bronchiectasis, chronic bronchitis, cystic fibrosis or agammaglobulinemia with bronchial disease. In addition, this procedure has been useful in acute bronchial obstructions such as postoperative atelectasis, and in bronchial obstruction associated with paralytic diseases such as Guillain-Barre disease. In the latter situation, the bronchial drainage procedure should be used together with catheter suction because of the inadequate coughing mechanism.

The procedure may be carried out by physical therapists, nurses, or their aides who have been instructed in the technique. Since many patients require a prolonged period of treatment at home it has been found useful to instruct parents, family members, or other nonprofessionals in the procedure. With careful instructions, supervision, and subsequent review of their application of the treatment, continued therapy at home has been maintained satisfactorily.

when it's late in life
and anxiety
and depression
coexist...

initial therapy
Triavil® 4-10

Each tablet contains 4 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride

maintenance therapy
Triavil® 2-10

Each tablet contains 2 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

appropriate
therapy in an
appropriate
dosage

During the years of declining strength and increasing infirmity, many patients are more sensitive to both the desired response and the unwanted effects of some drugs. That's when low-dosage therapy is needed. And that's when Triavil 4-10, as initial therapy, and Triavil 2-10, for maintenance, can prove particularly useful.

Starting with Triavil 4-10 should help minimize possible dose-related side effects in the geriatric patient with coexisting anxiety and depression. And, subsequently, Triavil 2-10 can increase flexibility in adjusting maintenance dosage.

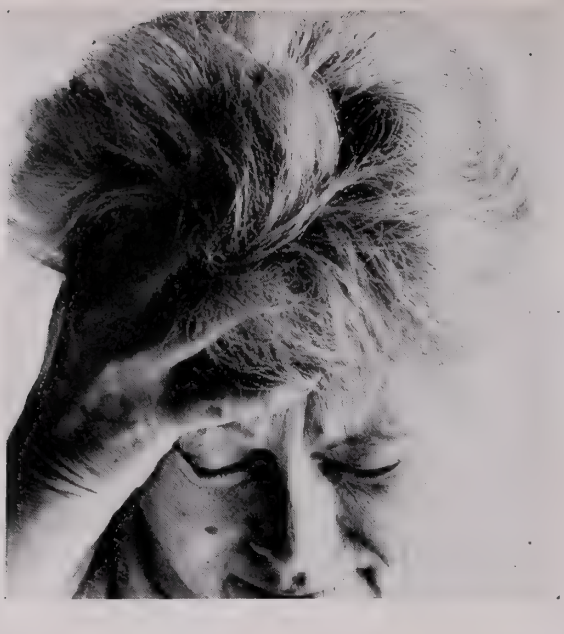
Activities made hazardous by diminished alertness should be avoided. You will want to inform your patients that the effects of alcohol may be potentiated. Because of the potentiation of other drug effects possible with MAO inhibitors, such agents should not be given concomitantly with Triavil. However, therapy with Triavil can be initiated cautiously two weeks or more after withdrawal of the MAOI drugs. And, until significant remission is observed, close supervision of any seriously depressed patient is, of course, essential to guard against possible suicide. The drug is contraindicated in glaucoma, in patients expected to experience problems of urinary retention, in drug-induced CNS depression, and in bone marrow depression.

Triavil 4-10 & 2-10—tranquilizer-antidepressant therapy especially appropriate for the elderly patient so often intolerant to medication in high dosages.

TRIAVIL®
containing perphenazine and amitriptyline HCl
TRANQUILIZER-ANTIDEPRESSANT

for moderate to severe anxiety with coexisting depression

For additional prescribing information, please see following page.



TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

TRIAVIL 4-10: Each tablet contains 4 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.
TRIAVIL 2-25: Each tablet contains 2 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.
TRIAVIL 4-25: Each tablet contains 4 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.
TRIAVIL 2-10: For use in adjusting maintenance dosage. Each tablet contains 2 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

for moderate to severe anxiety with coexisting depression

INDICATIONS: Patients with moderate to severe anxiety and/or agitation and depressed mood; patients with depression in whom anxiety and/or agitation are severe; patients with depression and anxiety in association with chronic physical disease; schizophrenics with associated depressive symptoms.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; urinary retention; pregnancy; glaucoma. Do not give in combination with MAOI drugs because of possible potentiation that may even cause death. Allow at least 2 weeks between therapies. In such patients therapy with TRIAVIL should be initiated cautiously, with gradual increase in the dosage required to obtain a satisfactory reponse.

WARNINGS: Patients should be warned against driving a car or operating machinery or apparatus requiring alert attention, and that response to alcohol may be potentiated.

PRECAUTIONS: Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having various modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Not recommended for use in children. Mania or hypomania may be precipitated in manic-depressives (perphenazine in TRIAVIL seems to reduce likelihood of this effect). If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Caution patients about errors of judgment due to change in mood.

SIDE EFFECTS: Similar to those reported with either constituent alone. **Perphenazine:** Should not be used indiscriminately. Use caution in patients with history of convulsive disorders or severe reactions to other phenothiazines. Likelihood of untoward actions greater with high doses. Closely supervise with any dosage. Side effects may be any of those reported with phenothiazine drugs: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); extrapyramidal symptoms (opisthotonos, oculogyric crisis, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; severe, acute hypotension (of particular concern in patients with mitral insufficiency or pheochromocytoma); skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; endocrine disturbances (lactation, galactorrhea, disturbances of menstrual cycle); grand mal convulsions; cerebral edema; altered cerebrospinal fluid proteins; polyphagia; paradoxical excitement; photophobia; skin pigmentation; failure of ejaculation; EKG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in the pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia; significant unexplained rise in body temperature may suggest intolerance to perphenazine, in which case discontinue. Antiemetic effect may obscure signs of toxicity due to overdosage of other drugs or make diagnosis of other disorders such as brain tumors or intestinal obstruction difficult. May potentiate central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol), atropine, heat, and phosphorous insecticides. **Amitriptyline:** Careful observation of all patients recommended. Side effects include drowsiness (may occur within the first few days of therapy); dizziness; nausea; excitement; hypotension; fainting; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of latent schizophrenia (however, the perphenazine content may prevent this reaction in some cases); epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration, or transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of mouth, blurring of vision, urinary retention, constipation, paralytic ileus; agranulocytosis; jaundice. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Before prescribing or administering, read product circular with package or available on request.

Disc Sensitivities in the Selection of Antibiotics*

JOHN M. MATSEN, M.D.†
Minneapolis, Minnesota

THERE ARE RELATIVELY few cases whereof one can say with surety that a certain antibiotic will inhibit or kill all strains of a particular bacterial species, independent of the body location where the strain may be causing an infection. To ascertain the appropriate antibiotic therapy for most types of bacterial infection, one must employ some method of determining which antibiotic and how much of it will be required to effectively eradicate the organism. This can be accomplished in most cases, however, by *in-vitro* testing.

Background

Of the three methods available,‡ the plate diffusion test employing antibiotic-impregnated paper discs seems the most utilitarian for the usual hospital laboratory and also for use in the physician's office, should conditions allow for some limited bacteriologic endeavors. Indeed, most clinical microbiology laboratories in this country now employ the paper-disc method using the commercially available discs.[2] For the purposes of this paper, all further discussion will pertain only to the plate diffusion method, using the paper discs.

Since the paper-disc method was first introduced,[3] a number of different protocols and methods have been advocated.[2-5] Other than differences in inoculum size or media used, the biggest variation of method has been in the use of the single disc or multiple discs for each antibiotic tested. The single high-potency disc method provides the most reasonable approach to disc testing and seems to offer the best correlation with dilution techniques.[1,2,6,7]

Disc Sensitivity

In all sensitivity testing methods, the size of the inoculum will affect the end result to a greater or lesser degree, depending on the method. The rigidity of standardization of the inoculum determines the reproducibility of zone readings. The use of the turbidity standard and the swabbing technique, as outlined subsequently, offers the greatest facility. Though variability may be slightly greater than with some other methods,[8,9] this variability does not unduly alter the final interpretation with respect to reproducibility, nor does it change beyond acceptable limits the interpretation of any single determination.

†Assistant Professor of Laboratory Medicine and Pediatrics, and Director, Diagnostic Microbiology Laboratories, University of Minnesota Hospitals.

‡The broth dilution, the agar dilution and the plate diffusion methods.

The medium used will also affect interpretation of results, due to production variability, diffusion differences and growth patterns. The medium recommended by the World Health Organization (WHO) expert committee[9,10] and by the proponents[2] of the method subsequently described is the Mueller-Hinton medium. As stated in the World Health Organization report:[10] "Mueller-Hinton medium was selected because of its good reproducibility, because of the positive experience of some members of the working party who have used it in their routine work, and because its production is potentially less variable than media which involve enzymatic digestive processes."

Sensitivity Technique

The disc-testing method used in the University of Minnesota Diagnostic Microbiology Laboratories is a slight modification of the method described by Bauer, Kirby, Sherris and Turck[2] of the University of Washington.

Five isolated colonies of an organism are picked from the original culture plate and are inoculated into a culture tube containing 3-5 ml of a suitable nutrient broth (Mueller-Hinton, tryptose phosphate, trypicase soy broths, etc.). Incubation then progresses for a sufficient period to allow for growth to be visible in the form of cloudiness or turbidity in the medium. This usually requires three to five hours, but the process may be enhanced for certain slow-growing organisms either by using a heavy initial inoculum or by longer incubation. An overnight broth culture may also be used. The culture suspension is then diluted to a density visually equivalent to that of a McFarland #0.5 standard. This dilution can be achieved by adding normal saline or water to the culture, or by adding a portion of the culture to a tube of saline. A McFarland #0.5 standard can be prepared by adding 0.5 ml of one per cent $BaCl_2$ to 99.5 ml of one per cent H_2SO_4 (0.36N).

Once the culture has been standardized, the Mueller-Hinton plate to be used should be streaked within 15 minutes by dipping a sterile cotton swab into the standardized and well-mixed suspension. The swab is rotated against the inside of the tube to remove excess suspension and is then streaked evenly across the Mueller-Hinton plate in three planes. Then the plates are allowed to sit for about five minutes to allow the inoculum to dry. The discs are then applied about 2 cm from the outer edge of the plate and sufficiently far apart so that inhibition zones do not overlap (about nine discs in the outer circle of discs on the 15 cm petri plate). Application is accomplished by means of applicators or with flamed and cooled forceps. The discs are then pressed firmly in place and the plates incubated. In this method it is important to incubate immediately so as not to alter results by allowing drug pre-diffusion, which will alter zone sizes.

Preparation of Plates

If one is to employ the method outlined here, it should be followed exactly; otherwise one cannot use with reliability the table included for interpretation. This method has been standardized using the large 15 cm petri plates. The use of regular 9-10 cm plates will probably result in a heavier inoculum, due to placing more organisms on a smaller surface area and thus introducing possible error in interpretation. The medium should be 5-6 mm in depth, necessitating the use of 65-75 ml of agar per 15 cm plate. Before being streaked, the plates should be dried for approximately 30 minutes in an incubator by inverting each plate and partially removing the cover portion which in the inverted position will be on the bottom. Ideally plates are used the same week they are prepared.

Discs

Discs should be obtained from a reliable supply house, where proper conditions of storage exist. It may be unwise to accept discs from drug company detail men due to the unknown aspects of the storage of their discs, since heat, freezing and thawing, and moisture can all hasten deterioration. All of these conditions may exist in the trunk of the detail man's car, depending on the season of the year.

Certain discs seem less stable than others. Notable in this regard are ampicillin and methicillin. We not infrequently receive from other laboratories specimens reported to be resistant to one or the other of these antibiotics, and testing with our discs and with dilution methods demonstrates strain sensitivity. We store our discs in the frozen state until we are ready to use them. While a cartridge is being used, it is kept in a desiccator bottle in the regular refrigerator. When removed from the refrigerator the discs are kept in the desiccator bottle until they have equilibrated to room temperature. This prevents moisture of condensation from forming in the cartridge and on the discs. After use the cartridge is replaced in the jar and re-refrigerated but never refrozen.

Incubation and Interpretation

Plates are incubated at 35-37°C overnight, and the diameters of the zones of inhibition around the discs are measured, using a ruler on the under surface of the plate or with calipers near the surface of the agar. In our laboratory we use the Fisher-Lilly Antibiotic Zone Reader (Fisher Scientific, No. 7-906 V2). After measuring zone size, one refers to the table of diameters (Table) to determine if the organism is

TABLE

Zone Size Interpretative Chart[2,11,12]

Antibiotic or Chemotherapeutic Agent		Disc Potency	mm Inhibition Zone Diameter to nearest mm		
			Resistant	Intermediate	Sensitive
Ampicillin	Gram-negative and enterococci	10 µgm	11 or less	12 - 13	14 or more
	Staphylococci and highly penicillin-sensitive organisms	10 µgm	20 or less	21 - 28	29 or more

Vancomycin		30 µgm	9 or less	10 - 11	12 or more

*Tentative standards.

†Urinary tract infections only.

‡Not applicable to blood containing media.

§Any of the commercially available 300 or 250 µgm sulfonamide discs can be used with the same standard of zone interpretation.

+This category includes some organisms such as enterococci which may cause systemic infections treatable by high doses of penicillin G.

sensitive, intermediate or resistant to the particular antibiotic being tested. The discs themselves measure 6 mm; hence no zone would be recorded as 6 mm. For measuring zones, the margins separating areas of visible growth and no growth are used for end points, except with the sulfonamides. Since organisms grow through several generations before inhibition with sulfonamides takes place, slight growth is disregarded and the margin of heavy growth (80% inhibition) is used for an end point. Bauer et al.[2] point out that this technique is satisfactory for sensitivity testing of all organisms against sulfonamides except group A beta-hemolytic streptococci. Spreading *Proteus* will form a thin veil of swarming around the discs. This swarming is disregarded, and one uses the margin of heavy growth for zone site measurement. If colonies appear within any inhibition zone, the culture should be checked for purity.

For testing *Hemophilus*, streptococci, enterococci, and certain other fastidious organisms, 5% sheep blood or human blood should be added to the Mueller-Hinton agar. The blood should be "chocalatized," or Fildes digest or Supplement B (Difco) added for *Hemophilus.*

The standards in the Table have been developed for rapidly growing pathogens. The slower-growing organisms have been less completely studied, but one can make the comment that due to slower growth, greater diffusion of antibiotics takes place. Thus, zones with these organisms tend to be larger, and this should be taken into account in interpreting results. It has been our experience that a 2 to 6 mm difference in zone size is not uncommon with organisms allowed to incubate only after pre-diffusion of the antibiotic has occurred. We therefore realize that such a deviation may also be manifest in the results obtained with slow-growing organisms.

Comments

It should also be pointed out that this method is considered invalid at present for testing *Neisseria gonorrhoeae.*[11] For sulfonamide testing of meningococci, the data of Bennett, Camp and Eickhoff[12] are used for zone size interpretation and are included in the Table.

If one uses a method based upon testing sufficient bacterial strains by comparing zone sizes with dilution studies, and if one has available the regression curves thus obtained, it is possible to relate zone size to minimal inhibitory concentration within a given range, depending on the scatter points on the regression curve for a specific antibiotic. For example, this is possible for us, using the regression tables worked out in our laboratory and in the laboratories of Dr. John C. Sherris.[11] These scatter-gram regression curves have been derived by using over 100 total strains of several different species of bacteria for each antibiotic.

The utility of this method is greatly enhanced by following the general protocol closely. The interpretive zone diameters in the Table have been closely worked out by using the agar dilution method for comparison,[2] and by relating the regression values to blood levels obtainable with the commonly used dosage schedules.

Antibiotics

The choice of antibiotics to be tested may be left entirely to the individual doctor; or they may be a matter of laboratory routine for gram-negative or gram-positive bacterial classes, or may be set by bacterial species. In our laboratory, if the physician has no preference of antibiotics to be tested, we employ routines dictated by the bacterial species to be tested.

Clinical Value

The clinical application evolves from the fact that all of us in clinical medicine deal with the use of antibiotics and are therefore in the position of using sensitivity data to guide our therapy. It would seem, then, that we would want to rely on the data we are receiving. Unfortunately, many laboratories do not use standardized methods for testing, and many do not have a solid basis on which to interpret the results of their particular method. Your familiarization with the need for a standardized method is hopefully enhanced at this point.

"The technique should be used exactly as described because, although it has considerable flexibility, changes in conditions may combine to produce inaccuracies; it should be particularly stressed that the zone sizes in the table are *only applicable to the use of Mueller-Hinton medium and to disc contents listed in the* *table.*"[2]

It would perhaps be in the best interests of the physician's clinical practice to become acquainted with the methods used in his hospital or commercial laboratory for sensitivity testing; even bolder yet, it may even be proper for him to insist on a standardized method based upon sufficient data to justify the interpretations reported.

Summary

For over-all ease, accuracy and utility the disc diffusion method of antibiotic sensitivity testing is the method of choice for most laboratories. However, to be able to report valid results, the method used must be standardized and based upon sufficient accumulated data to justify the interpretations and to insure reproducibility. The single high-potency disc method described herein meets these criteria and is currently in wide use in this country. Physicians relying on data from sensitivity testing should insist that there be justification of methods and reproducibility of results through standardization in any laboratory upon which they rely for sensitivity results.

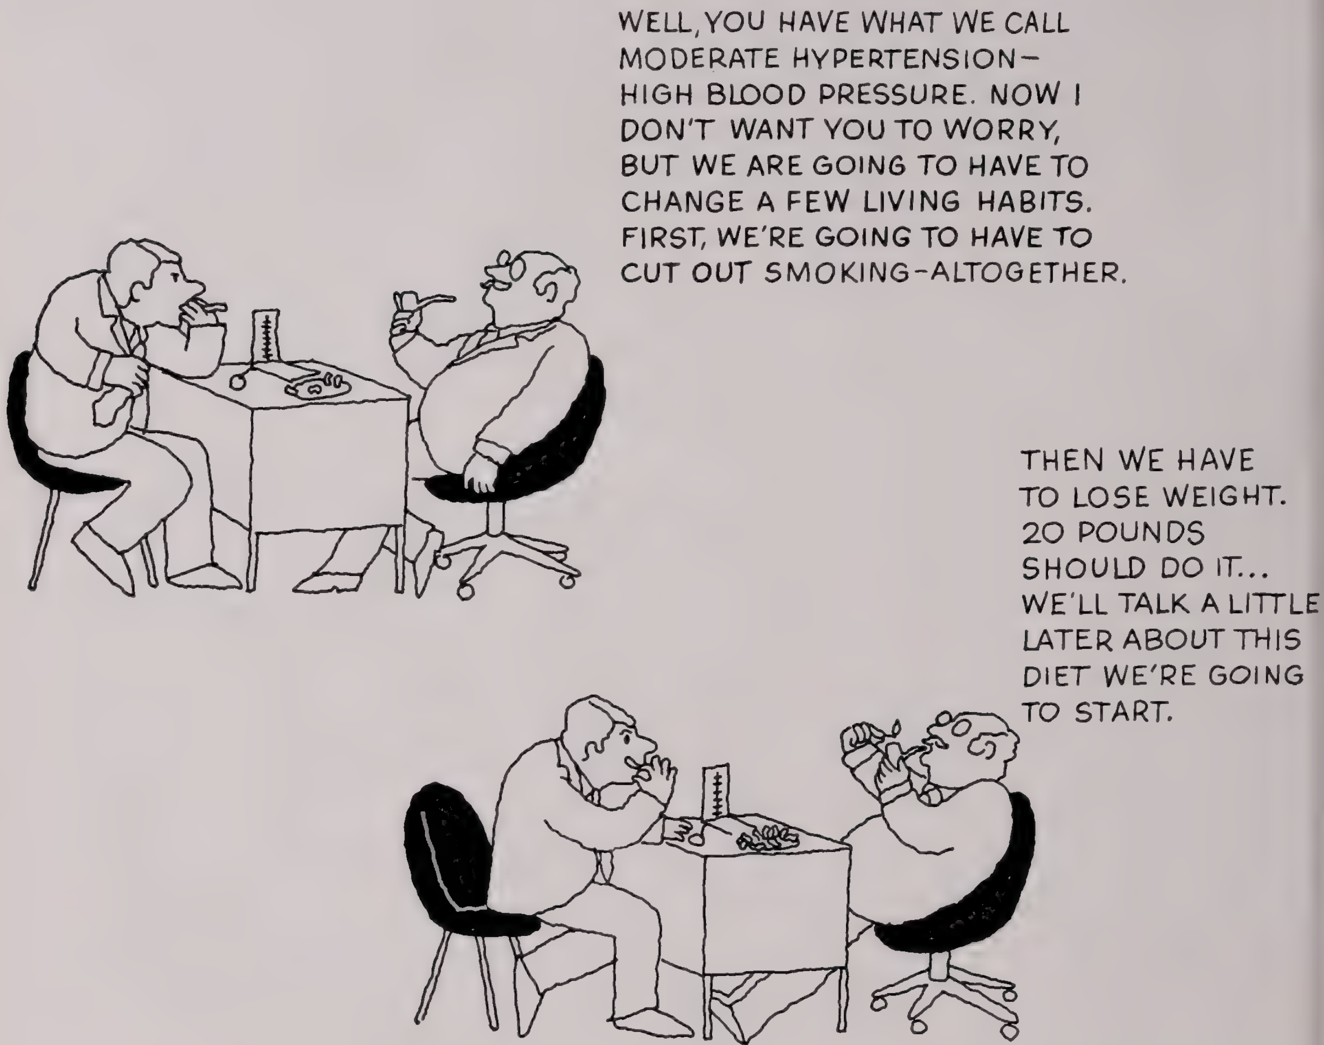
If nominated I will not accept; if elected I will not serve.—William Tecumseh Sherman, 1884

The Apprehensive Hypertensive



WELL, YOU HAVE WHAT WE CALL MODERATE HYPERTENSION— HIGH BLOOD PRESSURE. NOW I DON'T WANT YOU TO WORRY, BUT WE ARE GOING TO HAVE TO CHANGE A FEW LIVING HABITS. FIRST, WE'RE GOING TO HAVE TO CUT OUT SMOKING-ALTOGETHER.
THEN WE HAVE TO LOSE WEIGHT. 20 POUNDS SHOULD DO IT... WE'LL TALK A LITTLE LATER ABOUT THIS DIET WE'RE GOING TO START.

Regroton® to lower blood pressure

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Regroton®: chlorthalidone 50 mg., reserpine U.S.P. 0.25 mg. *Indications:* Hypertension. *Contraindications:* History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. *Warning:* With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly
other adverse reactions which have occurred in the adult. Increase
respiratory secretions, nasal congestion, cyanosis and anorexia ma
occur in infants born to reserpine-treated mothers. *Precautions:* Antihy
pertensive therapy with this drug should always be initiated cautious
in postsympathectomy patients and in patients receiving ganglion
blocking agents, other potent antihypertensive drugs, or curare. Reduc
dosage of concomitant antihypertensive agents by at least one-half. T
avoid hypotension during surgery, discontinue therapy with this age
two weeks prior to elective surgical procedures. In emergency surger
use, if needed, anticholinergic or adrenergic drugs or other supporti
measures as indicated. Because of the possibility of progression
renal damage, periodic kidney function tests are indicated. Discontinu
if the BUN rises or liver dysfunction is aggravated. Hepatic coma ma

corticosteroids, ACTH, or digitalis. Severe salt restriction is not recom-nended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. *Adverse Reactions:* The drug is generally well olerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (espe-cially when used with digitalis), drowsiness, dull sensorium, hypergly-cemia and glycosuria, hyperuricemia, lassitude, restlessness, transient nyopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocyto-penia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic itrophy and glaucoma, and pruritus. Eruptions and/or flushing of the kin, a reversible paralysis agitans-like syndrome, blurred vision, con-unctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. *Average Dosage:* One tablet daily with breakfast. *Availability:* Pink, single-scored tablets in bottles of 100 and 1000. Management-Comprehensive Treatment of Cystic Fibrosis*

LE ROY W. MATTHEWS, M.D.†
CARL F. DOERSHUK, M.D.†
Cleveland, Ohio

Cystic fibrosis has been defined as a generalized disease of the exocrine glands of the body involving the respiratory tract, the digestive and reproductive tract and the sweat glands, but recent tissue culture studies by Danes and Bearn[1] demonstrating the accumulation of metachromatic material in fibroblasts from patients with cystic fibrosis and their heterozygous parents (when grown in tissue culture) suggest that it is an even more generalized defect.

Truly successful treatment of this disease must await clearer definition of both the basic defects and the associated secondary abnormalities. In the meantime, our therapeutic efforts must be directed empirically against all the known manifestations of the disease, many of which are probably secondary to as yet unrecognized abnormalities. From what is known already, some of these abnormalities result from variable genetic make-up, but others are secondary to environmental factors, including exposure to infection, surgery, malnutrition, variations in therapy, and socioeconomic factors.

Treatment must be both individualized and comprehensive. All the manifestations of the disease as they appear in individual patients must be treated, and, where possible, the development of these manifestations should be prevented. A physician devoted to the practice of good preventive medicine can prevent or significantly delay many of the complications of cystic fibrosis such as malnutrition, fat-soluble vitamin deficiencies, intestinal obstruction due to fecal impaction, rectal prolapse, atelectasis, chronic obstructive pulmonary disease, and bronchiectasis. Because ninety percent of the morbidity and mortality associated with the disease results from secondary infection of the respiratory tract, therapy aimed at preventing such involvement markedly alters the course and the prognosis of the disease.[2]

Pulmonary Changes

All of the changes produced in the lungs tend to be self perpetuating (Figure 1). The initial lesion is an accumulation of secretions in the smaller bronchi and bronchioles which either impairs or results from impairment of the normal mechanisms of pulmonary hygiene. The changes such as regional hypoxemia in the respiratory tract that result from this lesion probably, in themselves, further impair the mucociliary mechanism. The resulting stagnation of secretions in the respiratory tract then leads to secondary infection which, in turn, stimulates an increased production of secretions, the addition of exudative products such as deoxyribonucleic acid to the secretions, increased obstruction due to mucosal edema and further impairment of ciliary activity as a result of mucosal inflammation. Obviously, this results in a vicious cycle with obstruction leading to infection and infection leading to more obstruction and increased infection. To be effective, therapy must be aimed at either preventing or breaking this cycle before irreversible damage results.[3] If one waits until irreversible changes such as squamous cell metaplasia, bronchiectasis and pulmonary fibrosis appear, the course of the disease becomes more progressive despite all currently available therapy.

Cystic fibrosis is a diagnosis that strikes terror into the hearts of most parents and often results in severe guilt feelings and great anxiety. The knowledge that a thorough evaluation was made before arriving at the diagnosis and before prescribing therapy does much to help the parents accept both. The period of hospitalization then provides an opportunity to use intensively all indicated therapeutic measures to bring the disease under control and to evaluate the individual patient's response to each. Such evaluation is essential if one is to avoid producing iatrogenic disease. Much can also be done during this period to allay the natural fears of the older child. Infants and young children's fears usually parallel the anxiety state of the parents and must be treated through them. Patient acceptance of a comprehensive and, where possible, prophylactic treatment program is extremely important. Most children will accept the mist tent, aerosol treatments, postural drainage and medications quite readily from trained hospital personnel. Those who resist can be slowly brought to acceptance with much less emotional stress when this is done by individuals who are less emotionally

involved with the child than the anxious, often guilt-burdened parents. Once this is accomplished, then the parents are brought into the treatment program and thoroughly instructed on their own children. Usually the child welcomes this change because he feels more secure in the hands of his parents. Only after the parents express confidence in their ability to carry out the therapy is the whole program transferred to the home.

Prevention of Progression

As with any chronic disease, if one is to be successful in preventing progression, it is essential that a close parent-patient-physician relationship be established. A thorough knowledge of what cystic fibrosis is, how it causes symptoms, what the symptoms mean, and how the treatment works will allay more fears than it produces and will greatly facilitate the establishment of an effective prophylactic home care program. To accomplish this, the physician must come down to the patient's and parents' level of understanding. He must use descriptive language. In talking about the normal mechanisms of pulmonary hygiene he must draw pictures, describe the normal mucus stream as a fast running mountain stream and that in the cystic fibrosis lung as a sluggish stream winding through a swamp. Bronchial obstruction can be compared to nasal obstruction with which everyone is familiar, coughing to nose blowing, the effects of neosynephrine in bronchi to its effects in the nose, and the lung to a balloon. Using this approach in a detailed fashion we have yet to see a family that could not understand the information presented, and we have had both parents and 12-year-old patients go home and deliver almost verbatim lectures to their local National Cystic Fibrosis Research Foundation chapters.

Inform the Child

A few families have attempted to keep the diagnosis from the child; such efforts have always been unsuccessful. These children then interpret the secrecy as ominous and live in silence with anxiety and fears of death that are often not justified by their condition. They become depressed and withdrawn or rebellious, but they usually do not reveal their knowledge to their parents. This situation deprives the child of very essential support and often leads to inadequate therapy. Every effort should be made to instruct the child at a level commensurate with his ability to understand. In discussing his condition it is usually advantageous to stress his good points and minimize his handicap. Many patients, especially teenagers, need subtle help in resisting the over-protective tendencies of their parents, in guiding their ambitions and in directing their activities into channels where the feedback will increase their sense of self importance and independence.

Family and Friends

Instruction of the patients, parents and older siblings or close relatives in the practical aspects of the therapeutic measures is extremely important, but it is equally vital that they understand how each measure works, what it accomplishes and why it is used. Certainly the knowledge that these measures are used prophylactically is essential both to decrease anxiety and to maintain the cooperation of the parents and the patients. It is also usually beneficial if the responsibility for long-term care is assumed by the physician, leaving the parents and patient only with the responsibility for day-to-day care.

Treatment

Prophylactic Therapy

Prophylactic therapy should include the measures aimed at assisting the normal mechanisms of pulmonary hygiene (aerosol and mist-tent therapy, postural drainage and physical activity), preventing viral pulmonary infections (measles and influenza immunizations), guarding against malnutrition and fat-soluble vitamin deficiencies, avoiding excessive sweating and the development of hyponatremia, and detecting pulmonary infection (frequent physician evaluation, bacteriologic and pulmonary function evaluations). Failure to control the gastrointestinal or sweat salt losses or to recognize the onset of diabetes or psychologic depression may have a marked effect on the pulmonary lesion and vice versa.

Clinically, cystic fibrosis is primarily a pulmonary disease and, as a result, the pulmonary lesion must be intensively treated. Most of these patients were found to have increased airway resistance, abnormal lung volumes and decreased arterial PO_2, indicating the presence of early pulmonary involvement. We have also demonstrated that treatment of these patients, with measures aimed at assisting the normal mechanisms of pulmonary hygiene in clearing their bronchial tubes, returns their lungs to more normal function. This is the chief reason we advocate the initiation of mist-tent therapy and the intermittent use of decongestant aerosols followed by postural drainage, as prophylactic measures. This probably results in over-treatment of a few patients, but there is no way currently available of identifying these few. It does not seem justifiable to sacrifice the majority to progressive pulmonary disease in order to avoid this over-treatment of a small minority.

Mist-Tent Therapy

Mist-tent therapy[4,5] is used to wet and thin the pulmonary secretions. In some patients propylene glycol may cause wheezing and evidence of bronchial irritation; in these instances an ultrasonic nebulizer used with half-strength normal saline provides an excellent fog, free of propylene glycol. To avoid any harmful effects mist-tent therapy should always be initiated and evaluated in the hospital before it is included in the home-care program. The jet-type nebulizer tents have been quite effective in most patients on prophylactic therapy and have the advantage of lower initial cost, ease of maintenance, and reliable operation. The ultrasonic nebulizer tents are more expensive, more difficult to maintain and less durable, but they are also more effective in the treatment of patients with significant chronic pulmonary involvement.

Aerosol Medication

Intermittent medication aerosol therapy is used to open up the respiratory tract, thus facilitating effective coughing and postural drainage. In general, 2 ml. of a solution containing nine parts 0.125% phenylephrine hydrochloride and one part USP propylene glycol are inhaled three to four times a day preceding postural drainage. Antibiotics should be added only when indicated. Depending on the size of the patient, 0.2 to 0.5 ml. of 1:200 solution of isoproterenol can be added to each aerosol, if indicated for bronchospasm.

Other medications occasionally used to treat the obstructive pulmonary manifestations include oral bronchodilators, and expectorants such as potassium iodide, hydriotic acid and iodinated glycerol. When the latter medications are used the patient should be closely observed for sensitivity reactions, goiter or hypothyroidism.

Postural Drainage Physiotherapy

Segmental postural drainage[6] with clapping and vibration of the chest provides effective drainage of bronchial secretions that have been thinned by mist-tent therapy, from the bronchial tree that has been opened by the aerosol decongestant and bronchodilator therapy. These measures complement each other and should be used together for maximum effects. In the hospital, postural drainage is performed three to four times daily following aerosol therapy. The duration must be adjusted to the tolerance of severely ill patients, but it should not be discontinued. Sometimes more frequent treatments for short periods of time are indicated. Patients with a pneumothorax, hemoptysis or cor pulmonale, and postoperative patients should be continued on intensive therapy since their survival depends on bringing their obstructive pulmonary disease under control. At home, prophylactic drainage of each segment is recommended twice daily. Localized disease or significant generalized involvement requires more intensive and longer treatment of the more involved areas. For all patients deep breathing and coughing are important parts of the postural drainage routine and should be encouraged in each position.

Physical Activity

Physical activity is another important aid in preventing the accumulation of secretions in the bronchial tree. Confinement to bed should be avoided even during hospitalization. Small infants, postoperative or severely ill patients should be turned and positioned frequently. For ambulatory patients, dancing, running, swimming, athletic activities and active play should be encouraged.

Management of Sequellae

Chronic Sinusitis

Patients with cystic fibrosis almost invariably develop chronic sinusitis; about 10% develop nasal polyps, and a significant number develop allergic asthma. The sinusitis should be treated with both topical and oral decongestant therapy; a few patients require sinus drainage.

Allergic Diseases

Local therapy is generally unsuccessful in the treatment of nasal polyps, but allergic desensitization therapy may decrease the rate and incidence of recurrence. When nasal obstruction occurs polypectomy is indicated. Asthma is a serious complication which must be thoroughly evaluated and intensively treated. Environmental and dietary allergens must be identified and eliminated if possible. Bronchodilators, by both aerosol and systemic routes, should be used, and also steroid therapy if indicated.

Obstructive Airway

In a small group of infants with cystic fibrosis who present with severe peripheral airway obstruction due to edema, congestion and bronchospasm, but without significant evidence of infection, steroid therapy may be life-saving. When intensive pulmonary therapy does not quickly initiate improvement in such infants, steroids in a dosage equivalent to 10-12 mg. per kilogram per day of cortisone may be extremely effective in breaking the vicious cycle. These infants probably do not have asthma since, with subsequent continuation of the usual therapeutic measures, the wheezing does not recur. All such patients should be watched carefully for evidence of pulmonary infection and treated vigorously with antibiotics if it appears.

Therapy of the Pulmonary Infection

Obviously, all of the previously mentioned therapy has been directed primarily at the accumulation of secretions and the obstructive lesion in the bronchial tree. This therapy was deliberately discussed first, because we believe it is more closely related to the basic defect in the respiratory tract and is essential for effective treatment of the secondary bacterial infection.

Identify Sensitivities

In cystic fibrosis, Staphylococcus aureus, Pseudomonas aeruginosa, Hemophilus influenzae, Proteus vulgaris, Escherichia coli or Klebsiella pneumoniae organisms[7,8] are noted for their tendency to cause low-grade chronic infection and for their tendency to become resistant to the more commonly used antibiotics. In patients with early pulmonary involvement and with staphylococcal or hemophilus influenza infections complete clearing of the infection should be the goal and may require two to 12 weeks of intensive antibiotic therapy. During this period the agent or agents used should be changed to match the changing bacterial flora and sensitivities, which should be reevaluated at weekly intervals. If the patient does not show a definite response to such therapy the presence of L-forms of staphylococci[9] should be suspected and treatment with lincomycin or erythromycin prescribed.

Pseudomonas Organisms

Early in the course of cystic fibrosis the Pseudomonas organisms isolated are usually sensitive in-vitro to tetracycline, chloroamphenicol, sulfisoxasole, carbenicillin, streptomycin, colistin, polymyxin, and neomycin. Intensive treatment with these drugs may eradicate the organism in patients with little or no irreversible damage in their bronchial tree, but elimination is rarely if ever possible in patients with more advanced disease even though marked clinical improvement may occur. In some patients continuous infestation with Pseudomonas does not appear to further damage the lungs, but in most it is pathogenic and produces progressive damage. Rapid progression in such patients may occur if antibiotic therapy is withheld. In patients with advanced pulmonary disease continuous high-dosage antibiotic therapy is often necessary to maintain control of the infection. In many patients the presence of two or three varieties of pathogenic organisms with differing antibiotic susceptibility requires the use of more than one antibiotic. As the disease advances the predominant flora becomes Pseudomonas organisms sensitive only to polymyxin, colistin, gentamicin and carbenicillin. The latter is still available only for investigational use. Carbenicillin is a synthetic penicillin which can be given parenterally in high dosage without producing toxic effects. We have now used this antibiotic on 42 patients with advanced disease, most of whom have shown significant clinical and pulmonary function test improvement but failure to clear the Pseudomonas. A non-toxic truly effective antibiotic for the treatment of Pseudomonas bronchial infections remains the greatest need in therapy.

Follow-up Treatment

After the initial period of intensive hospital treatment further antibiotic therapy depends on follow-up outpatient evaluations at four to six-week intervals. Bacterial pulmonary infection may develop despite the most intensive efforts to maintain good pulmonary hygiene. The primary purpose of the follow-up evaluations is the early detection of recurrence of either the obstruction or the infection.

Detect Early Signs of Infection

To accomplish this a careful interval history covering the patient's general activity, any respiratory or pulmonary symptoms, and the effectiveness of therapy should be obtained. Special attention should be paid to the minimal symptoms and signs of early, low-grade infection including fatigue, irritability, decreased appetite and exercise tolerance, increased cough or development of a night cough, signs of air-trapping, rales, wheezing, an increase in respiratory rate and failure to gain weight or actual weight loss. Fever and toxicity are rarely encountered. When such evidence of infection is found and the routinely obtained throat or sputum culture reveals a significant pathogen, full-dosage antibiotic therapy is prescribed for a minimum of two weeks and up to three or four weeks or longer, if necessary. In those patients who have no chronic pulmonary symptoms and who have only normal flora on culture no antibiotic therapy should be employed. Resistant Pseudomonas infections may respond to high-dosage tetracycline (100 mg/kilogram) even when in-vitro antibiotic sensitivity studies indicate resistance, but they may also require repeated hospitalization for parenteral colistin, gentamicin or carbenicillin therapy.

Pancreatic Deficiency

Comprehensive therapy requires attention to the pancreatic deficiency found in over 85% of patients with cystic fibrosis. Treatment is aimed at providing an adequate caloric intake. Small infants may require up to 200 calories per kilogram per day. A fat-free diet should be avoided in infants under one year of age since essential fatty acids should not be excluded during this period of rapid growth. Solid foods should be added early. The older child should be kept on a high protein diet with fat restricted according to tolerance. Rigid dietary control is not necessary, but in many cases excessively fatty foods should be avoided. In some patients high-calorie snacks including a preparation containing medium chain triglycerides may be helpful.

Therapy for Deficiency of Digestive Enzyme

In the patients with a demonstrable deficiency of pancreatic digestive enzyme function, pancreatin therapy results in improved digestion and absorption.

Pancreatin Preparations

Several satisfactory pancreatin preparations (one to three capsules or one to two packets per feeding), Viokase (one half to two tsp. or two to 10 tablets per feeding) or Panteric Granules (one half to one tsp. or two to six capsules per feeding) is usually effective. We prefer Cotazym because it is generally effective in a smaller dosage, is better accepted by the patient and produces less odor in flatus, urine and stools. This is extremely important to the child who is embarrassed by the teacher calling recess every time he passes flatus or the comments of his classmates after he uses the rest-room facilities.

Bile Salts

Selected patients show further improvement in the degree of steatorrhea and in stool consistency when bile salts are added in the form of Convertin, Cotazyn B or Accelerase (one to two tablets or capsules per meal). A few patients and/or parents manifest an allergic response to pancreatin. Such patients may be treated with Papase. Infants with cystic fibrosis may be erroneously diagnosed as having asthma and treated with soybean formulas. If meat or some other high-quality protein is not added to the diet such infants may present with hypoalbuminemia and gross edema.

Vitamins and Salt

To prevent vitamin A, D, E, and K deficiencies from influencing the course of the disease we routinely prescribe water-soluble multivitamin preparations in twice the usual daily dosage. Because autopsy studies of patients with cystic fibrosis have revealed ceroid* pigment in the smooth muscle of the intestinal tract and degenerative changes in skeletal muscle and because clinical studies of vitamin E have revealed very high requirements in these patients, Aquasol E is prescribed in a dosage of 50 mg. per day under two years of age and 100 mg. per day thereafter.

Because excessive amounts of sodium and chloride are lost in the sweat of cystic fibrosis patients during hot weather, febrile illnesses and strenuous exertion, sodium chloride in doses of one to five grams per day is prescribed.

Complications

Other complications of cystic fibrosis must be constantly watched for. Acute intestinal obstruction or meconium ileus equivalent, biliary cirrhosis with bleeding from esophageal varices, ascites or hypersplenism, diabetes and growth failure or delayed puberty all require early detection and treatment. Finally, psychological problems are frequently encountered. Every effort should be made to recognize such problems early and to deal with them, utilizing all available community resources including social workers, psychiatric social workers, psychologists and, if necessary, psychiatrists. Vocational rehabilitation counselors are often very helpful in dealing with teenagers and young adults.

Clinical Studies

For the past 12 years we have attempted to provide a comprehensive and where possible prophylactic treatment program for all of our patients with cystic fibrosis. During the 10 years from July 1, 1957, through June 30, 1967, 404 patients with cystic fibrosis were admitted to this program (Table 1) for a total of 1677 years of follow-up care.

Thirty-seven of these patients died during the 10-year period, yielding a crude mortality rate of 2.2%.

Evaluation of Prophylactic Program

Several years ago we published our results on five years' experience with this treatment program on the first 98 consecutive patients seen.[3]

TABLE I
Ten Year Mortality

	Followed	Consultation
Number of patients seen	404	50
Patient years of follow-up	1677	
Number of deaths	37	7
Mortality rate/year of follow-up	2.2%	

All of these patients have been evaluated at frequent intervals using modified Shwachman and Kulczycki[10] criteria, grading them from 0 to 25 points for each of the four categories: (1) General Activity, (2) Physical Examination and Cough History, (3) Growth and Nutrition, and (4) X-ray Examination of the Chest (Figure 2).

0-25	**General Activity:** School attendance, play activity, exercise tolerance, personality.
0-25	**Physical Examination and Cough:** nature and severity of cough, chest findings, clubbing and cyanosis, pulse and resp. rate.
0-25	**Nutrition:** Weight and height percentile, dietary and stool history, muscle mass and strength.
0-25	**X-ray Findings:** Emphysema, atelectasis, fibrosis, bronchial markings, cavitation, cyst formation, infiltration.

Fig. 2—Clinical evaluation criteria used for grading all patients initially and at six-month intervals. Scores of 0-25 points were assigned for each of the four categories, a perfect score being 100 points.

Early and Reversible Involvement

These patients were divided into two groups using the relatively objective x-ray score. The 49 patients who presented with an x-ray score of 19 or more points of a possible 25 or who responded to therapy and subsequently attained such a score at any time during the follow-up period were considered to have early and reversible pulmonary involvement and to be on prophylactic therapy. Objective data collected on these patients, including growth and weight changes, morbidity and mortality, and pulmonary function studies, showed good correlation with the clinical evaluations. No evidence of significant progression of the pulmonary lesion was observed by any criteria for the prophylactically treated group. Indeed, mean pulmonary function test results for these patients were well within the range of normal values even at the end of the average four-and-a-half-year-follow-up period at an average age of seven years. No deaths occurred in this group. This study gave great impetus to the concept that early diagnosis and a prophylactic approach to treatment are essential for control of the pulmonary lesion of cystic fibrosis.

---

*See Test Your Word Score Page 1401.

The remaining 49 patients never attained an x-ray score over 18 points and were considered to have irreversibly damaged lungs requiring therapeutic management. The overall mortality rate of less than 2% per year of follow-up with no deaths under six years of age indicated the effectiveness of the therapeutic program.

Follow-up

These 98 patients were reevaluated as of June 30, 1967, at the end of 10 years' experience with the treatment program. Only three of the 98 had been lost to follow-up and one other had transferred to another center for the previous two years. Fifteen had died. The remaining 79 patients continued on therapy and returned regularly for follow-up evaluations.

The clinical parameters, physical examination, chest x-ray and total score for the 49 patients who achieved a chest x-ray score of 19 or more points at some time during follow-up and were thus considered to be on prophylactic care, were evaluated for the period from one year on treatment to June, 1967. The one-year score was selected because maximum improvement on therapy is seen in most cases by then. The evaluation was aimed at determining the effectiveness of therapy in preventing progression after maximum benefit was obtained. Three of the original 49 patients in this group were lost to follow-up after 37 to 54 months. The total mean period of therapy for the remaining 46 patients was eight years, 10 months (range six years four months to 10 years). The mean initial physical examination score, which was 16 points, rose to 21 points at one year and remained at 21 points at the end of the follow-up period. The mean initial score for x-ray was 17 points, rose to 21 points after one year and remained at 20 points in follow-up. Only two patients deteriorated by more than four points. The mean initial total score which was 66 points rose to 87 points at one year and remained at 86 over the follow-up period. Six patients were improved by more than five points, 28 remained unchanged (± 5 points) and only 12 showed deterioration of more than five points from their one-year to most recent score. Five of these patients showed decreases of more than 10 points.

For the 49 patients whose pulmonary involvement was severe enough (x-ray score never greater than 18 points) to require therapeutic management, the mean period of follow-up was six years, eight months (range two years to 10 years). This period was shorter because of the deaths which occurred in this group. Their mean initial score for physical examination, which was 11 points, improved to 16 points after one year and fell to 12 points by June 30, 1967. For this group the mean initial score for x-ray, which was eight points, improved only to 10 points and fell again to eight points. Their mean total initial score, which was only 48 points, rose to 63 after one year and then fell to 53 points at the end of the ten-year period. Over 50% (28 of 49) were worse by more than five points.

These clinical evaluation studies revealed a significant difference between the two groups of patients. Those started on therapy before irreversible damage to their lungs had occurred showed little or no tendency toward progression of their pulmonary lesion. In contrast, significant progression was seen when the same or more intensive therapy was provided after significant pulmonary involvement had occurred.

Mortality

There was only one death in the group of patients treated prophylactically. She was a patient who was severely ill until diagnosed at age two years, who improved dramatically on therapy for five years, then failed gradually and died of pulmonary complications at eight and a half. In contrast, there were 14 deaths in the patients requiring continuous therapy. The mean initial x-ray score for these 14 patients was only seven points, and only one was above 13 points.

The more objective pulmonary function test data (Table 2) substantiates the results of the clinical evaluations. Since many patients were too young for accurate testing when first seen, the results of tests obtained after 12 to 18 months of treatment or when the patient was age five to six years were used and compared to the previous test results. For the patients who died, the last test prior to severe deterioration was used.

Conclusions

This data lends further support to the hypothesis that effective therapy is possible only when the diagnosis is made before significant irreversible damage has occurred in the lungs and when currently available therapeutic measures are used to prevent the development of chronic infection and associated destructive changes. Life table data offers additional support for this concept and also shows the overall value of comprehensive therapy.[11]

TABLE 2

Pulmonary Function Test Results

Chest x-ray group	19 to 25		0 to 18

The Perennial Proneness

The respectable medical historian, Fielding H. Garrison, referred to a "fetishistic instinct," a "primitive craving for the supernatural which is ever latent in man." This craving he saw as a common aspect underlying primitive medicine and modern quackery. . . Rabbits' feet afford a steady market in America, at prices ranging from a dime to five dollars. Charms, voodoo bags, and love potions have been said to bring in a million dollars a year from residents of Alabama, Mississippi, and Louisiana alone. And a Missouri root doctor found customers for three magical remedies, a cathartic, an emetic, and—as he called the third—a "rank pizen," all made from the very same root. Hibobalorum was prepared by peeling the bark downward, Lobobahirum by peeling it upward, and Hi-lo-bustem by peeling it around.*

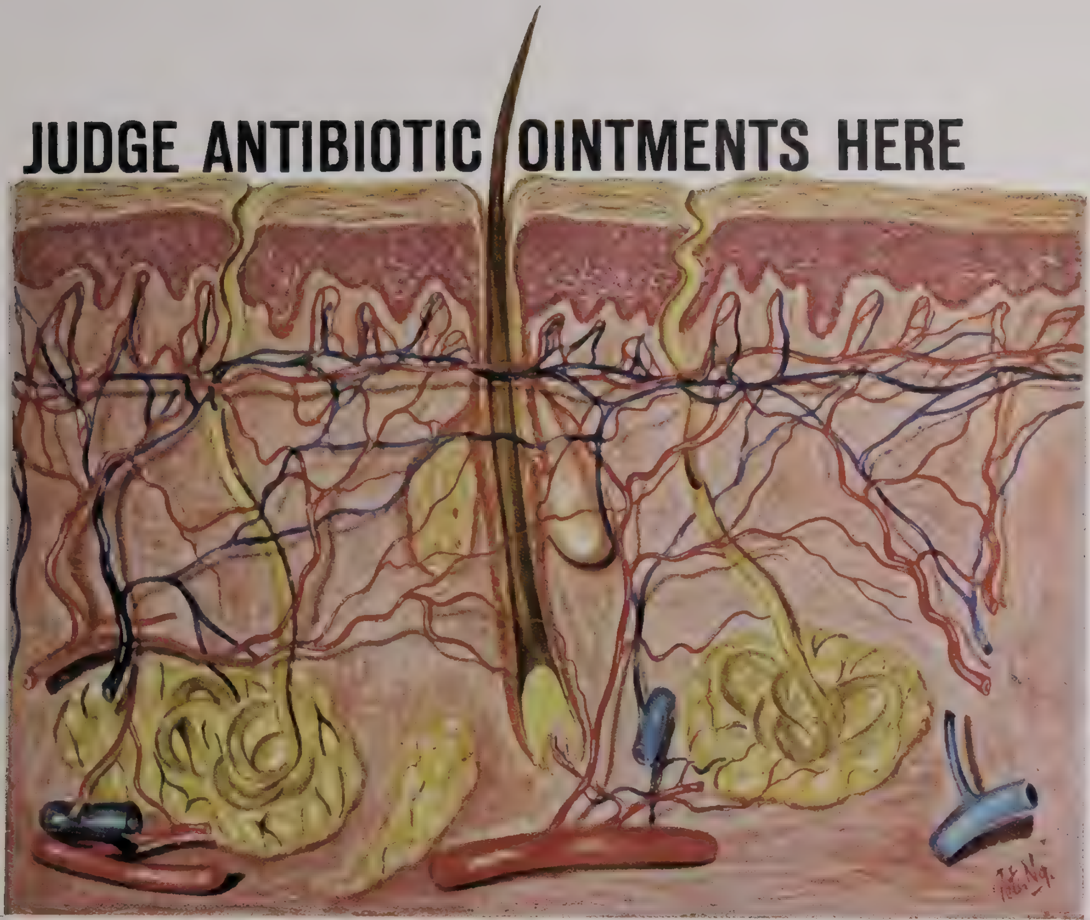
A bachelor gets tangled up with a lot of women in order to avoid getting tied up to one.—Helen Rowland

JUDGE ANTIBIOTIC OINTMENTS HERE



Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B —bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

Clues to PVD

The heavy smoker with vasospasm

He may be comparatively young or approaching middle age. Typically, he is a heavy cigarette smoker—a pack or more a day for a number of years. Whether smoking is a causative or an important exacerbating factor in peripheral vascular disease is still under discussion. But the vasoconstrictive effects of nicotine are firmly supported by a substantial body of laboratory and clinical evidence, and the close association is now generally accepted.

Thus, a history of heavy smoking coupled with vasospasm may serve as warning signals to the physician. When a diagnosis is established, therapeutic measures are directed toward increasing the local circulation, and appropriate management of the patient's general medical needs should be instituted. These include the important safeguards of keeping warm and refraining from smoking.

Before prescribing Roniacol Timespan (nicotinyl alcohol tartrate), please consult complete product information, a summary of which follows.
Indications: Conditions associated with deficient circulation; *e.g.*, peripheral vascular disease, vascular spasm, varicose ulcers, decubital ulcers, chilblains, Meniere's syndrome and vertigo.
Caution: Roche Laboratories endorses caution in the administration of any therapeutic agent to pregnant patients.
Side Effects: Transient flushing, gastric disturbances, minor skin rashes and allergies may occur in some patients, seldom requiring discontinuation of the drug.
Dosage: 1 or 2 Timespan Tablets morning and night.
How Supplied: Timespan Tablets—150 mg nicotinyl alcohol in the form of the tartrate salt —bottles of 50.

mportant in
otal management of
eripheral vascular disease,
ascular spasm or
hilblains Roniacol®
Timespan®
(nicotinyl alcohol tartrate)

or relief of ischemic symptoms

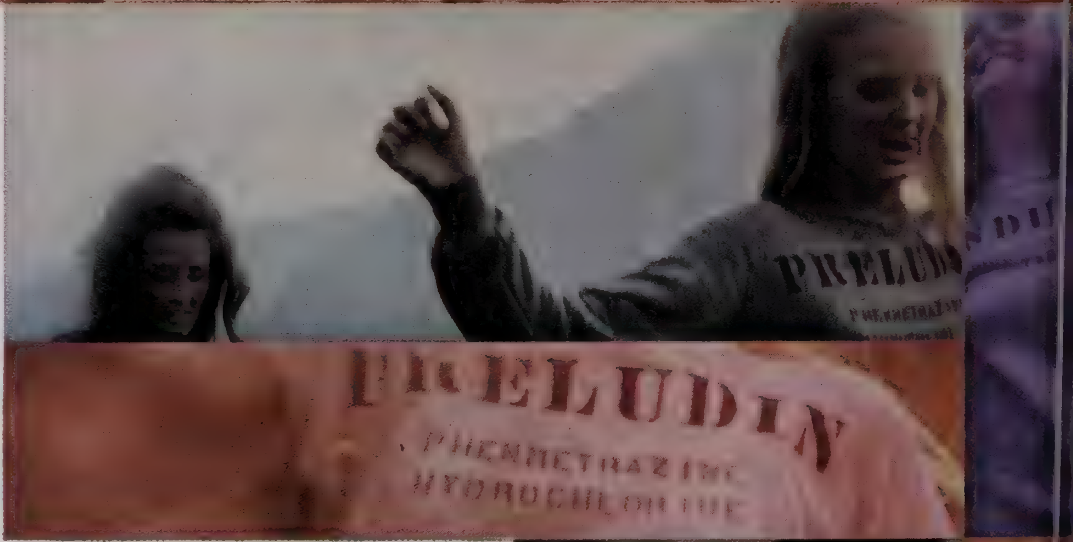
nvenience of b.i.d. dosage—sustained-release Timespan Tablets usually provide longed relief of ischemic symptoms with two doses daily.

oothness of onset—the action of Roniacol (nicotinyl alcohol) is smooth and dual in onset, rarely causing severe flushing.

lectivity of action—relaxes the musculature of peripheral blood vessels.

gh degree of safety—side effects seldom require discontinuation of therapy.

PRELUDIN
PHENMETRAZINE
HYDROCHLORIDE
ENDURETS
PROLONGED - ACTION
TABLETS



Preludin®
phenmetrazine hydrochloride

Preludin is indicated only as an anorexigenic agent in the treatment of obesity. It may be used in simple obesity and in obesity complicated by diabetes, moderate hypertension (see Precautions), or pregnancy (see Warning).
Contraindications: Severe coronary artery disease, hyperthyroidism, severe hypertension, nervous instability, and agitated prepsychotic states. Do not use with other CNS stimulants, including MAO inhibitors.
Warning: Do not use during the first trimester of pregnancy unless potential benefits outweigh possible risks. There have been clinical reports of congenital malformation, but causal relationship has not been proved. Animal teratogenic studies have been inconclusive.
Precautions: Use with caution in moderate hypertension and cardiac decompensation. Cases involving abuse of or dependence on phenmetrazine hydrochloride have been reported. In general, these cases were characterized by excessive consumption of the drug for its central stimulant effect, and have resulted in a psychotic illness manifested by restlessness, mood or behavior changes, hallucinations or delusions. Do not exceed recommended dosage.
Adverse Reactions: Dryness or unpleasant taste in the mouth, urticaria, overstimulation, insomnia, urinary frequency or nocturia, dizziness, nausea, or headache.
Dosage: One 25 mg. tablet b.i.d. or t.i.d. Or one 75 mg. Endurets tablet a day, taken by midmorning.
Availability: Pink, square, scored tablets of 25 mg. for b.i.d. or t.i.d. administration, in bottles of 100 and 1000.
Pink, round Endurets® prolonged-action tablets of 75 mg. for once-a-day administration, in bottles of 100 and 1000. (B)R3-46-560-B

Meetings and Announcements

American Medical Writers Association

The North Central Chapter of the American Medical Writers Association meeting November 1, 1969, 1:00 P.M., Judd Hall, Mayo Clinic, Rochester, Minnesota. Social hour and dinner, New Sheraton, Rochester, 7:30 P.M. All doctors interested in medical writing are welcome, wives included.

University of Minnesota

Fourth Annual Symposium on Kidney Disease

The University of Minnesota will conduct a course for the Upper Midwest Chapter of the National Kidney Foundation on September 20, 1969. Half of the program will be devoted to urinary tract infection and the other half to a discussion of transplantation and its implications for the local practitioners.

Hypnosis in Medicine

The University of Minnesota will conduct a course in Hypnosis in Medicine to be offered on September 25-27, 1969. The course will be co-sponsored by the American Society of Clinical Hypnosis Education and Research Foundation and the Minneapolis Clinic. The course is designed to familiarize practicing physicians with the uses of hypnosis in clinical medicine. For further information on the above courses contact: Lee D. Stauffer, College of Medical Sciences, Box 193, Mayo Building, University of Minnesota, Minneapolis 55455.

Mayo Clinic Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery will be held at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Identical sessions are offered on November 3, 4, 5, 1969 and November 10, 11, 12, 1969.

This program is acceptable for credit by the American Academy of General Practice and the College of Family Physicians of Canada. The registration fee for this program is $20.

The number of physicians who can be accommodated is necessarily limited. For this reason identical programs will be offered two successive weeks. The program will be presented first on November 3, 4, 5, and repeated on November 10, 11, 12. Those wishing to attend should communicate with M. G. Brataas, Mayo Clinic, Rochester, Minnesota 55901, indicating which session they would prefer to attend.

Stroke Conference

September 19-20, Pick-Nicollet Hotel, Minneapolis, Minnesota. Conference—sponsored by The American Rehabilitation Foundation. Sessions include measurements of improvement in completed stroke, rehabilitative predictors in completed stroke, environmental correlates of differential outcomes, and implications for future research. Fee: $20; registration open to all disciplines. Contact: Dr. Thomas P. Anderson, 1800 Chicago Avenue, Minneapolis 55404.

Southern Minnesota Medical Association Meeting

Southern Minnesota Medical Association Meeting in Albert Lea, Minnesota, September 13, 1969, Inn Towne Motel (Heritage Hall). For details contact Dr. John J. Eustermann, Mankato Clinic or Ethel McClane, 1726 No. 4th St., Mankato.

Pulmonary Complications of Cystic Fibrosis[*]

HARRY SHWACHMAN, M.D.[†]
DOUGLAS S. HOLSCLAW, M.D.[†]
Boston, Massachusetts

THE CHIEF CAUSE of death in cystic fibrosis remains the pulmonary failure that results from the progression of the pulmonary lesion. We believe it is the rare patient with cystic fibrosis who escapes involvement; however, there are a small number who survive for many years with mild disease.

The pathogenesis of the pulmonary lesion in cystic fibrosis has been described (Figure 1). This is not a step-by-step sequence involving the entire lung at the same time; rather each one of these various steps is occurring in many different locations throughout the lung at any given time. This is further modified by varying degrees of severity in any one individual. Other more subtle changes occur, including metaplasia of the normal columnar ciliated epithelium of the bronchus into mucus-producing cells, which results in the increased elaboration of the abnormally viscous mucus and interrupts the usual upward flow of secretions secondary to loss of ciliated cells. In addition, infection results in focal obliteration of other ciliated cells and increases mucus production.

We shall now consider separately some of the pulmonary complications that may occur.

Air Trapping and Emphysema

Many factors combine to cause this, such as the ball valve action of mucus which partially blocks a bronchus, mucosal edema secondary to inflammation, bronchospasm on an irritative or allergic basis and restriction in the mechanics of ventilation because of the fibrosis and scarring that have taken place. At times, this emphysema can assume alarming proportions (Figure 2), with the A-P diameter of the chest being greater than the lateral. Although usually a slow insidious process, at times there may be rather acute changes in the chest configuration, especially in the infant. The residual volume of the lung increases, although the total lung capacity may not be increased due to lack of aeration of other areas of the lung.[1] The end result is a fixed, overdistended, restrictive chest which reduces the effectiveness of the cough so vitally important to these patients.

Bleb-Bullae-Pneumothorax

Another extension of chronic air trapping is the formation of subpleural blebs and bullae formation, a variable degree of which can be seen on the surface of the lungs, especially at the apices. At times these bullae can reach massive proportions (Figure 3). Considering the frequency with which these are found and the size to which some of them may grow, it is remarkable that so few rupture under the stress of forceful paroxysms of coughing. Spontaneous pneumothorax is becoming a considerable problem, especially in young adults with cystic fibrosis.[2] We have now encountered 88 episodes of pneumothorax in 46 different patients (Table 1) in our clinic over the past 18 years. Approximately 2,000 patients with cystic fibrosis were observed during this period. The right and left sides were involved almost equally and

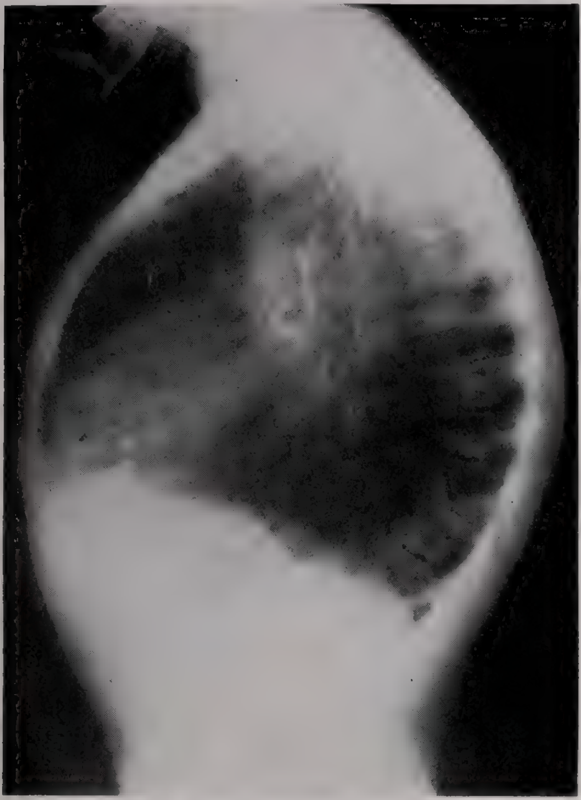

Fig. 2—Lateral chest film of a 13-year-old girl showing marked increase in anterior-posterior diameter and severe air trapping.

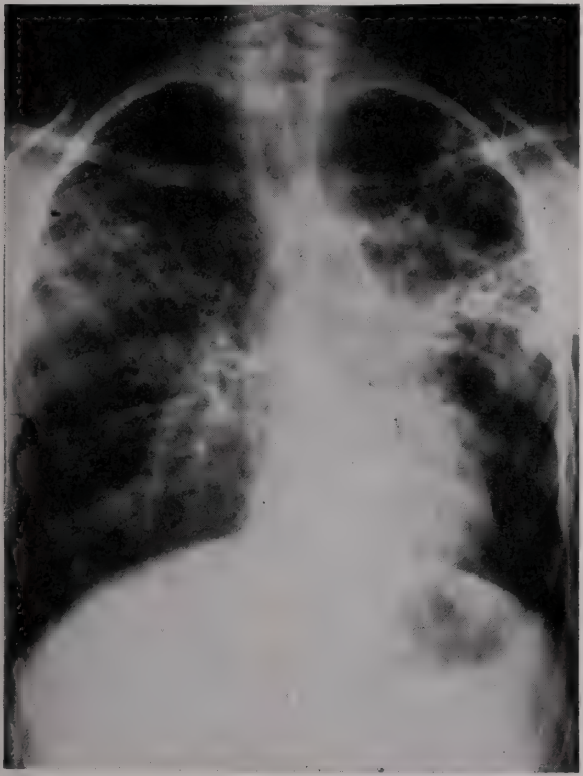

Fig. 3—Multiple large bullae have formed at both apices, compressing adjacent lung parenchyma.

there were eight instances of simultaneous bilateral episodes. The extent of the pneumothorax ranged from a minimal asymptomatic accumulation of pleural air to total collapse of a lung (Figure 4) at times with evidence of tension. At the time of the first episode of pneumothorax, the average age was 14 years and five months. Forty-two of the episodes were recurrences in 21 (45%) of the patients; half of the recurrences took place in the opposite hemithorax from the original. Most of the patients had moderate to severe pulmonary involvement prior to the initial episode. No specific precipitating factor could be identified. Some occurred while at rest or asleep; some while coughing; some with exercise; two with changes in altitude, and four related to the use of intermittent positive breathing apparatus. The majority of the patients (two thirds) were treated by tube thoracostomy.

There was a significant mortality associated with a pneumothorax (Table 2). Fifteen patients expired while hospitalized for a pneumothorax, or during a hospitalization in which a pneumothorax occurred. Seventeen patients died at a later date without signs of a pneumothorax, and 14 are currently alive. The average

duration of time from the initial episode to death in 32 patients was 16 months.

On occasion pneumomediastinum will occur with or without a pneumothorax, and can spread as subcutaneous emphysema.

Lobar Atelectasis

A more complete or advanced form of mucus plugging results in lobar atelectasis. In young infants this commonly occurs in the right upper (Figure 5) or right middle lobe, although all segments may be involved.[3] A vigorous attempt should be made to re-expand the collapsed lobe or segment since the certain end result will otherwise be bronchiectasis and abscess formation. Atelectasis may occur following measles, pertussis or other infections, a fact which supports the need for early and complete prophylactic immunization against such conditions.

Atelectasis can involve an entire lung as well as a single lobe. In older patients this usually takes the form of a gradual collapse in a severely diseased lung over a period of several months (Figure 6). Large A-V shunts may develop so that the lung tissue is poorly perfused as well as poorly ventilated. If feasible, pneumonectomy should be performed.

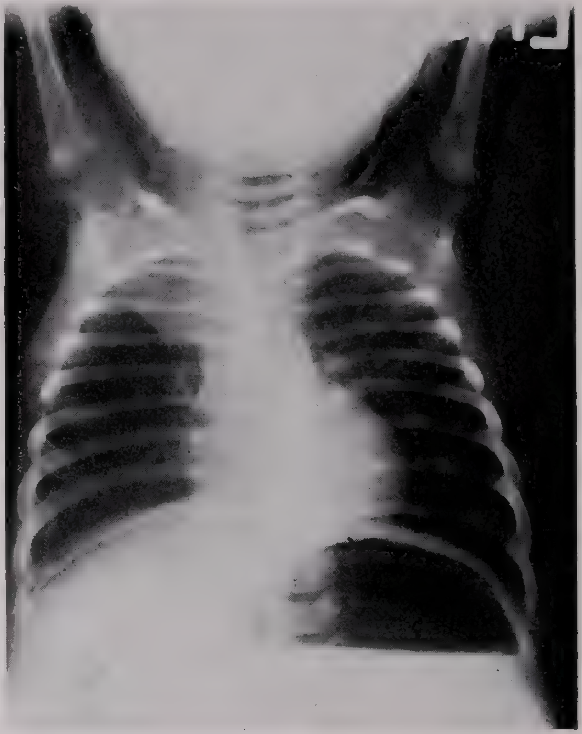

Fig. 5—Right upper lobe atelectasis in an infant, age six months, which was present when the patient was first seen and the diagnosis made. This collapse did not require resection.

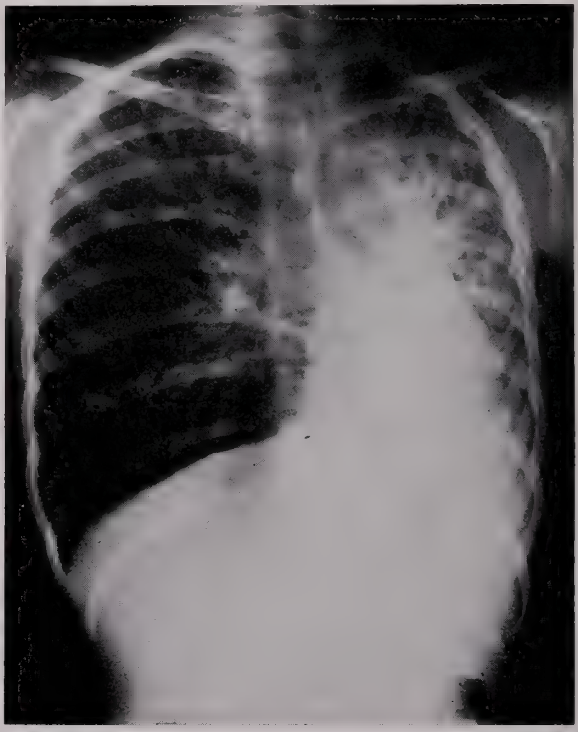

Fig. 6—Almost total collapse of the left lung with herniation of the right lung across the mediastinum. The collapse had gradually occurred over a two-year interval. Pneumonectomy followed.

Bronchiectasis

This takes place in collapsed areas of lung as well as in local areas when bacterial invasion and destruction of the bronchial wall have occurred. Bronchitis and stagnation of the accompanying secretions and exudate are two essential factors in the development of bronchiectasis. Characteristically, the bronchiectasis is multifocal and distributed throughout all lung fields. This is seen quite frequently in the upper lobes in contrast to the predominantly lower lobe distribution which is seen in the bronchiectasis which occurs in non-cystic fibrosis patients.[4] By x-ray, all anatomical variants of bronchiectasis are present (Figure 7): saccular, fusiform, or cylindrical. This widespread dis-

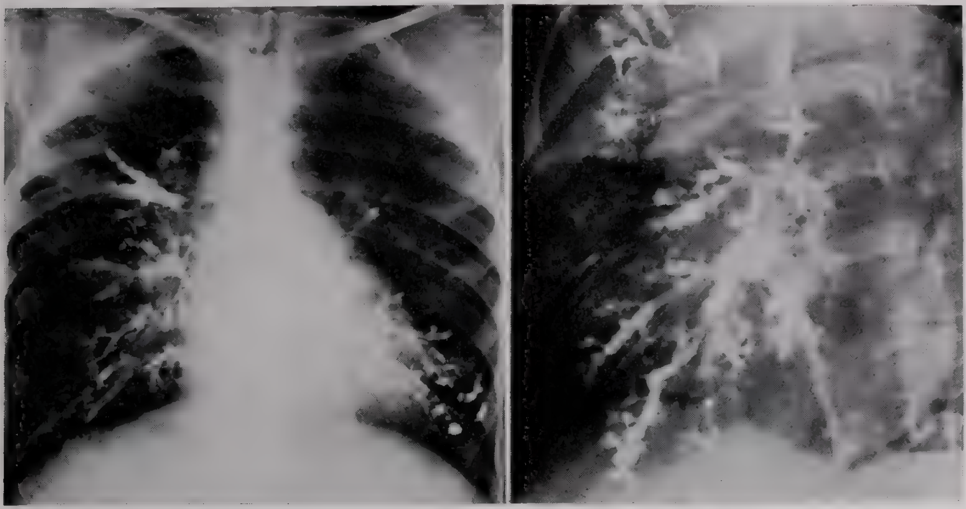

Fig. 7—Bronchograms revealing the multiple and widespread areas of involvement by bronchiectasis in a 14-year-old male.

tribution makes surgical resection impractical except for those cases where the disease is localized. When possible, surgical resection should be attempted[5] since the profuse exudate and secretions intensify the disease involving the remainder of the lung.

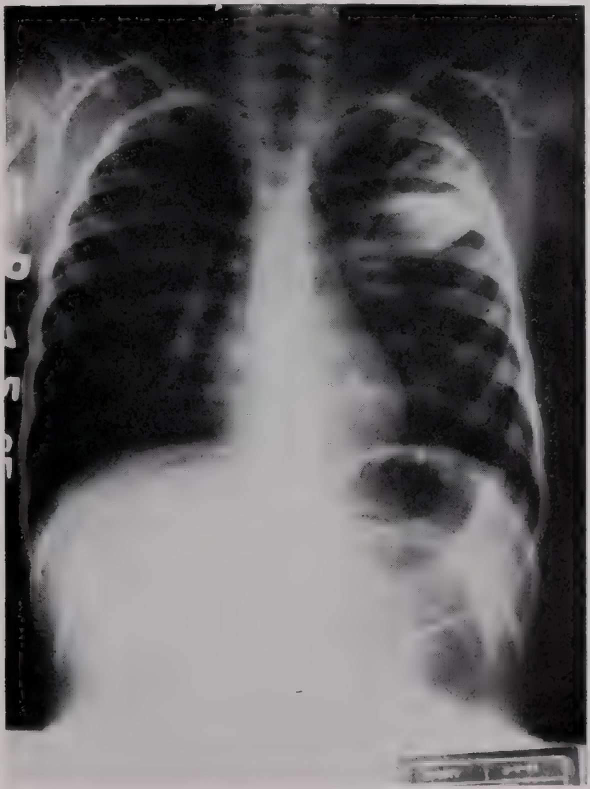

Fig. 8—Large left upper lobe abscess cavity with an air-fluid level. Note the relative absence of disease in the remaining lung fields. Treated by resection.

Hemoptysis

A direct consequence of the bronchial wall destruction associated with bronchiectasis is erosion of the surrounding bronchial and pulmonary arteries, resulting in massive hemoptysis. This complication is becoming increasingly more frequent, particularly in older patients with cystic fibrosis[6] (Table 3). The first blood-streaking in the sputum occurred at a mean age of 15 years, and the mean age of the initial massive hemoptysis was 18 years. In six patients the bleeding episode was the terminal event, death occurring immediately in four patients and within two days in another two. The cause of death was either immediate exsanguination or asphyxiation by the aspirated bronchial secretions. In all, 11 of the 16 patients had died within six months of their initial hemorrhage, indicating the severity of this complication and the poor prognosis which it carries. No particular precipitating factor could be identified, nor could any part of the pulmonary treatment regimen that they were receiving be incriminated. Over half the episodes, however, were associated with a pulmonary exacerbation. In all cases, the invading organisms were the Staphylococcus and Pseudomonas.

Routine chest films, bronchograms and bronchoscopy are of little help in localizing the site of the bleeding. Frequently, the patient is able to localize the site subjectively by a sense of warmth, or a bubbling, gurgling sensation a few seconds prior to the bleeding. At present, our only treatment has been limited to replacement of blood volume and symptomatic measures including vitamin K intravenously. In view of the serious prognosis, however, if the patient can be stabilized and a fair assessment of his pulmonary reserve made, perhaps surgical resection would be the desirable form of definitive therapy.

TABLE 3

Massive Hemoptysis in Cystic Fibrosis

1. 25 episodes in 16 patients
2. Average age onset blood-streaking 15 years
3. Average initial massive bleeding 18 years
4. 11/16 died in six months after initial bleeding
5. 13/25 associated with pulmonary exacerbation

Abscess

Although small abscesses very commonly occur in cystic fibrosis, large cavitary abscesses are rare. As a result of incomplete resolution of a large area of bronchopneumonic consolidation or by extension of the bronchiectatic process, on occasion a large pulmonary abscess will form. For some unexplained reason, three patients presented with large abscesses measuring between 30 to 40 millimeters with fluid levels during the summer of 1966. We had not seen this particular type of lesion prior to that time. These three required surgical resection. Two additional cases seen since then have responded to medical management. There may be an unexplained tendency for these large abscess cavities to recur in the same patient but in a different area. These patients had either normal or elevated gamma globulin levels. Our treatment has been massive and prolonged antibiotic therapy followed by surgical resection if resolution does not occur.

Fungal Abscess and Overgrowth

Related to localization and abscess formation is the rare patient with cystic fibrosis who develops a fungal mycetoma. This is most commonly due to *Aspergillus; Candida* and *Actinomyces* are seldom the etiologic agent. The

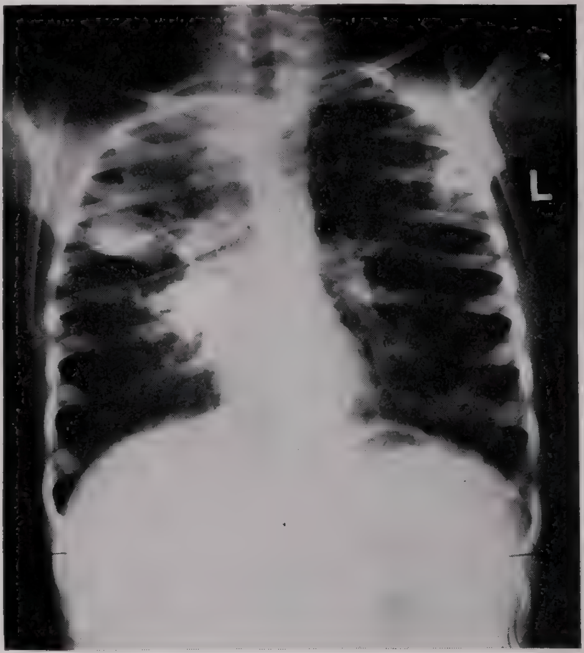

Fig. 9.—Circumscribed right upper lobe aspergilloma in a 14-year-old boy. Note the apical pleural cap. *Aspergillus* isolated repeatedly from the sputum.

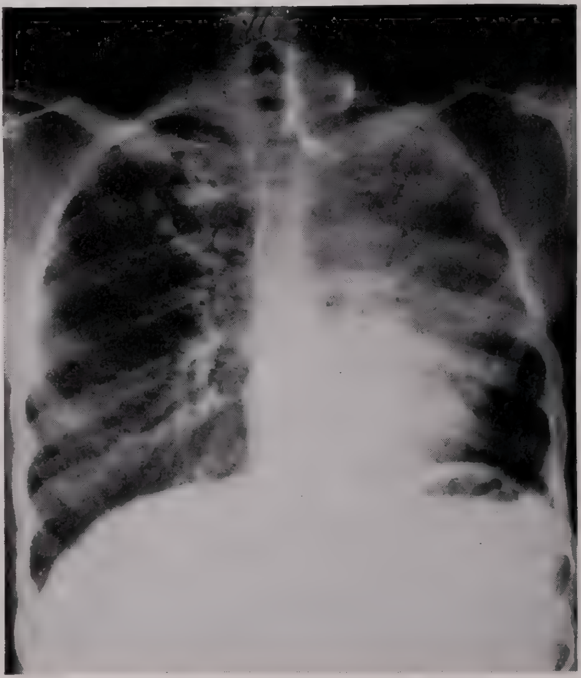

Fig. 10—Acute, hazy, diffuse left lung infiltrate in a 19-year-old boy. Eosinophiles of 28%. Positive sputum culture for *Aspergillus*.

Aspergillus may become localized as an aspergilloma (Figure 9) or can take a disseminated form as an acute infection, aspergillosis (Figure 10). There is a marked increase in the number of eosinophiles in the peripheral blood with fever and copious sputum production. In our cystic fibrosis clinic, some 31% of patients will have a serum-precipitating antibody titre against *Aspergillus* antigen, but very few at any one time will have *Aspergillus* cultured from their sputum.[7]

Botryomycosis

This is a rare and poorly understood chronic granulomatous process which bears a superficial resemblance to actinomycosis. The most common site is in the lungs, but the lesion may spread to adjacent structures. The clinical diagnosis is difficult unless drainage sinuses appear, and is usually made by pathological examination either on resected specimens or at postmortem. Fungal cultures are negative, but there is a constant finding of the bacteria *Staphylococcus aureus* or *Pseudomonas aeruginosa*. We have encountered this in seven patients, only two of whom are still living. This condition is an exception to the unique ability of the patient with cystic fibrosis in general to localize infection and prevent dissemination.

Empyema

Considering the 80-90% prevalence of

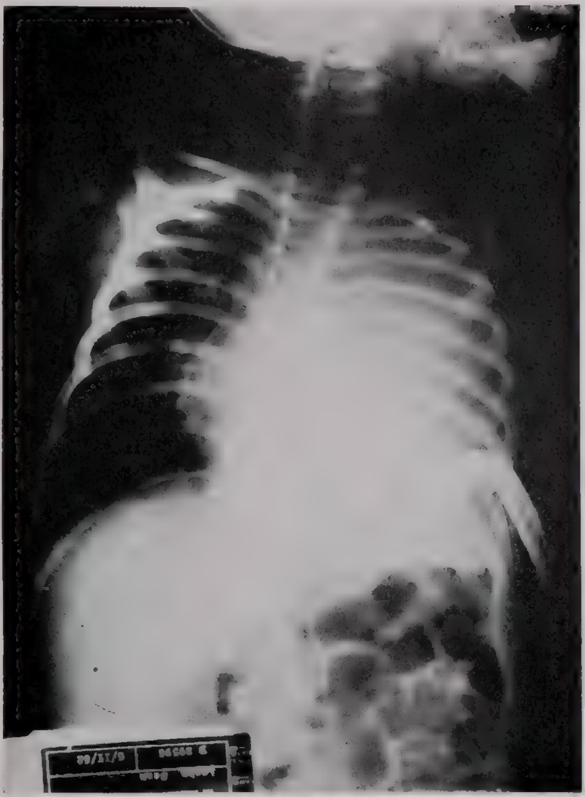

Fig. 11—Six-month-old boy with a massive left pleural effusion being treated by tube drainage. Has no localized sequellae now at age eight years.

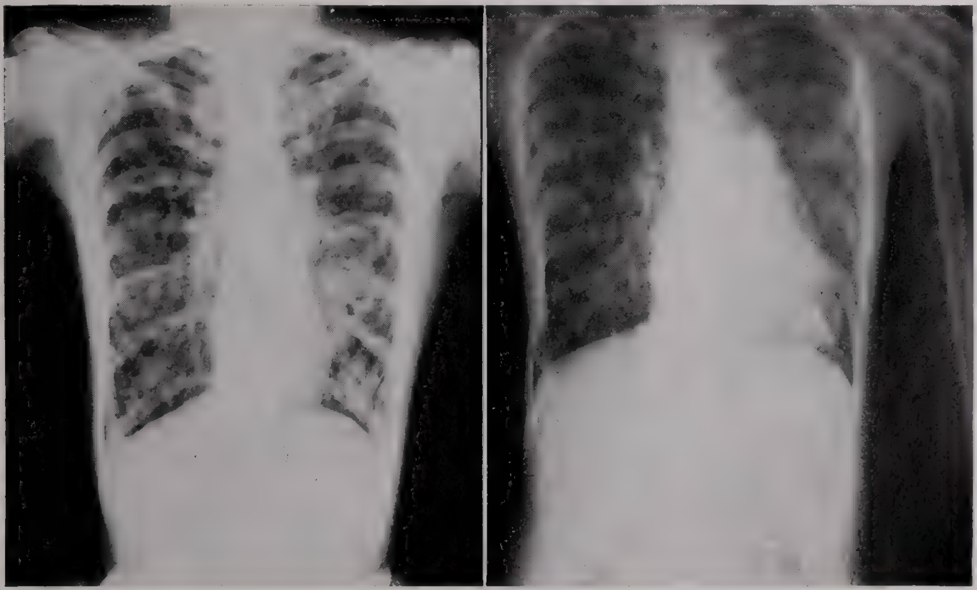

Fig. 12—Acute cardiac dilatation which took place over a six-week interval in an 18-year-old girl with severe advanced pulmonary disease.

Staphylococcus aureus in the sputum in the early stages of the disease, it is remarkable that childhood staphylococcal pneumonia with pneumatoceles and empyema occur so seldom today in patients with cystic fibrosis (Figure 11). Over half of our patients in whom this has occurred are from three to nine months of age when the serum gamma globulin levels are at their physiological lowest. All have required tube thoracotomy drainage and have shown few sequellae related to the empyema itself.

Cor Pulmonale

Finally, the end result of many of the above pulmonary complications, either singly or in tandem, produces enough pulmonary hypertension to cause right heart failure or cor pulmonale.[9] The early stages of this are difficult to detect clinically since an enlarged liver, distended neck veins, right ventricular hypertrophy on electrocardiogram, rales and an increased respiratory rate may all be due to the severe pulmonary disease alone. X-ray evidence of dilatation of the main pulmonary arteries and of progressively increasing heart size (Figure 12) is accurate and practical in the early diagnosis of cor pulmonale. This finding, coupled with peripheral edema, carries a very poor prognosis, with death usually resulting within six months.

Conclusion

Although these severe complications are associated with a high mortality, the general prognosis of cystic fibrosis is steadily improving. The establishment of the diagnosis shortly after birth plus a constant therapeutic and supportive program has extended the life span into the young adult years in over 70% of patients.[10]

Pulmonary Failure in Asthma and Cystic Fibrosis*

JOHN S. RYDBERG, M.D.†
Minneapolis, Minnesota

MANY SYSTEMIC and pulmonary diseases terminate in the final common denominator of respiratory failure. The term respiratory failure has different connotations because respiration involves two separate and distinct processes. The first of these, external respiration, is the gaseous exchange that takes place in the lungs and involves the movement of oxygen from the atmosphere into the blood and the movement of gaseous wastes from the blood into the atmosphere. The second process is termed internal respiration and comprises the exchange of oxygen between blood and body cells, cellular utilization of the oxygen, and removal of the waste products of oxidation by the blood. In this discussion we will focus our attention on failure of the first process, external respiration and, to avoid confusion, use the term *pulmonary failure.*[1]

Clinical Manifestations

The function of the pulmonary system is to secure gas exchange between blood and ambient air in order to maintain blood gas tensions within normal limits. From a functional viewpoint pulmonary failure is the impairment of gas exchange to such a degree that arterial blood gas tensions depart from these limits.

Hypoxia

This is a laboratory, rather than a clinical definition, but it is necessary because the clinical manifestations of hypoxia, which include restlessness with impairment of mental function and judgment, hypotension, tachycardia and cyanosis, are not specific enough for precise diagnosis. Unfortunately even central cyanosis—the blue color of the mucous membranes where blood flow is high—is not a reliable sign even under the best conditions.

Hypercapnea

Pulmonary failure may also be manifested as hypercapnea. The clinical symptoms and signs of hypercapnea are also of little help in the diagnosis of pulmonary failure. They include headache, dizziness, confusion progressing to unconsciousness, twitching, hypertension and sweating. Campbell cautions that the only symptom regularly present in hypercapnea is a disturbance of consciousness;[2] Christie states: "The diagnosis of carbon dioxide . . . is a matter of knowledge and of laboratory technique rather than of clinical acumen."[3]

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Department of Anesthesiology, University of Minnesota Health Sciences Center, Minneapolis, Minnesota.

Arterial Oxygen and Carbon Dioxide Tension

Because the clinical manifesations of hypoxia and hypercapnea are of little help in the diagnosis of pulmonary failure, clinicians and physiologists must utilize laboratory blood gas measurements. Most authors agree that pulmonary failure is present when there is an acute lowering of arterial oxygen tension to less than 50 mm Hg or an acute elevation of arterial carbon dioxide tension to greater than 50 mm Hg.[2,4,5] Thus the lungs fail in terms of function.

Recent technical developments make the determination of arterial blood gas quickly available and accurate. The technique of arterial puncture can be mastered by anyone who can do a venipuncture. For repeated determinations the placement of an indwelling arterial catheter is recommended. The measurement of arterial oxygen tension (PaO_2) by the Clark membrane-covered polarographic electrode is simple and reliable. The arterial carbon dioxide tension ($PaCO_2$) may be calculated by measuring pH and the CO_2 content of the blood. The Severinghaus electrode permits direct measurement of the arterial carbon dioxide tension. In many medical centers resident and intern physicians have effectively used both the O_2 and CO_2 electrodes.

Evaluation of Therapy

When one has diagnosed pulmonary failure he is well on the road to therapy. The basic principle of treatment in acute pulmonary failure is to deal with potentially reversible features while providing support to correct hypercapnea and hypoxemia. In planning therapy one must evaluate three factors: (1) the nature and severity of the underlying disease; (2) the precipitating factor in pulmonary failure; and (3) the correctable aspects of the crisis.

The remainder of the discussion is concerned with the mechanisms and therapy of pulmonary failure in two diseases: bronchial asthma and cystic fibrosis.

Bronchial Asthma

The American Thoracic Society defines bronchial asthma as "a disease characterized by an increased responsiveness of the trachea and bronchi to various stimuli, and manifested by widespread narrowing of the airways that changes in severity either spontaneously or as a result of therapy."[6] The fundamental functional disturbance in bronchial asthma is airway narrowing or obstruction due to hypertrophy of the smooth muscle, glands and mucosa in response to allergen-antibody stimuli.

The disease occurs in about 3 per cent of the United States' population and the incidence is about the same in children and adults. The old adage, "He who has asthma pants on to a ripe old age," is a misconception; of approximately 4,900 persons who died of asthma in 1962,[5] 216 were less than 20 years old.[7] Pediatric fatalities as the result of this potentially reversible disease are regrettable occurrences.

Mechanism of Failure

The bronchial obstruction of asthma makes the movement of air into and out of the lungs more difficult. During ventilation, air moves from an area of greater to an area of less pressure; on inhalation, air passes through the airways into the alveoli because muscular forces have enlarged the chest and decreased alveolar pressure. The reverse situation occurs during exhalation. The French physician, Jean Marie Poiseuilli, did much to explain why patients with bronchial narrowing have so much trouble breathing. He studied the relationships of various factors to the volume of flow through a tube and derived the equation:

$$\dot{V} = \frac{Pr^4}{8\ lN}$$

where

$\dot{V}$ = volume of flow per second (cm^3/sec)
P = the difference in pressure between the two ends of the tube (dynes/cm_2)
r = the radius of the tube (cm)
l = the length of the tube (cm)

N = the coefficient of viscosity (poises). Examination of this law indicates that the flow through a bronchiole depends on changes in the radius and in the pressure, since viscosity and length do not change appreciably.

A specific example may demonstrate the importance of maintaining an adequate radius of the lumen of the airway. If there is no change in the pressure differential along a bronchus and the radius is decreased by one half, the volume of flow is reduced to 1/16 of the previous value (1/2 to 4th power is 1/16). Obviously decreasing the bore of the airway by such things as bronchospasm, mucosal edema and secretions has a drastic effect on the volume of ventilation. Thus, if the patient can increase the pressure change 16 times he will achieve the same volume of inspiration as if he had no decrease in bronchial radius. The narrowed airway also results in the usual passive exhalation becoming an active process requiring additional energy expenditure. The patient must ventilate even more to supply the increased oxygen needs of the respiratory muscles required by the extra work.

When the expiratory force fails to expel the inspired tidal volume, trapping of air occurs in the lung; as a result the diaphragm is displaced downward and mechanically becomes less efficient in its work. The anteroposterior diameter of the resting lung is increased and the respiratory muscles are less efficient. Under resting conditions only about 1 per cent of the body's energy expenditure is due to the work of breathing. With the exaggerated respiratory efforts of status asthmaticus and the inefficiency of the muscles, 30 to 40 per cent of the body's energy expenditure may be for the work of breathing.[8]

Heart failure may result from the patient's inability to expel the inspired tidal volume; the alveoli become hyperinflated and increase the resistance of the pulmonary capillary bed through which the right heart must propel its blood. Indeed, Miyamoto[9] found that asthmatic children showed a tendency toward right ventricular failure.

The injudicious use of sedation may lead to carbon dioxide retention. Moderate sedation long has been considered an important aspect of treatment since anxiety and agitation may contribute to CO_2 production and ventilatory insufficiency. The use of barbiturates, tranquilizers, and opiates may be beneficial, but the degree to which a small dose of such agents can depress respirations of a patient in pulmonary failure must be recognized. In fact, sedatives and tranquilizers are contraindicated in the management of severe asthma unless ventilation is supported, since their administration has been incriminated as an important contributory factor to death.[10,11]

Precipitating Causes of Failure

Viral or bacterial infection of the respiratory tract is a frequent precipitating cause of acute pulmonary failure, especially in children less than one year of age.[10] Richards found that 31 per cent of pediatric patients with status asthmaticus had pneumonitis when admitted to the hospital,[10] and Lanoff pointed out that pneumonitis was a leading cause of death in asthmatic children.[7]

Clinical Indications of Failure

Downes and Wood[12] listed the following clinical signs as indications of acute pulmonary failure in patients with status asthmaticus:

1. Severe inspiratory retractions
2. Absence of inspiratory breath sounds
3. Generalized muscular weakness
4. Decreased level of consciousness and response to pain
5. Cyanosis in 40 per cent ambient oxygen
6. Arterial carbon dioxide tension of 65 mm Hg or higher.

They stated that at least three of these criteria were necessary to establish a diagnosis of pulmonary failure, but the most useful sign was an increased arterial carbon dioxide tension.

Treatment of Pulmonary Failure in Asthma

The correction of hypoxia and hypercarbia is of prime importance in the treatment of pulmonary failure. If the patient is apneic or gasping, assisted ventilation must begin immediately. Mouth-to-mouth resuscitation should be instituted until appropriate equipment can be secured. If possible, 100 per cent oxygen should be supplied to the patient by intermittent bag breathing through a face mask from an anesthesia machine or from a portable resuscitator connected to oxygen. If exhalation is prolonged and incomplete, gas exchange may be facilitated by gentle manual compression of the thorax during exhalation to help expel air trapped in the lung;[12] such assisted ventilation with high flows of oxygen may sustain life for hours. In patients who are obstructed or poorly cooperative the insertion of an artificial airway is mandatory.

Ventilation

Mechanical ventilation is the most effective management of prolonged pulmonary failure. A *tracheostomy* or *endotracheal tube* is essential for its effective use.[13] In children, nasotracheal intubation is preferred because it is easily and rapidly undertaken even in difficult locations; it produces fewer complications and when improvement occurs in the patient's condition the tube can be easily removed.[10,13] With *nasotracheal intubation* there is no wound to bleed or become infected and less danger of surgical pneumothorax than with tracheotomy; however, the endotracheal tube is prone to cause subglottic edema after extubation. Otherwise the incidence of complications from the two methods of maintaining an airway is about equal.

Once intubation is accomplished the patient is usually connected to a pressure breathing apparatus. This unit provides a number of therapeutic approaches to the problem of hypoxia and hypercarbia:

1. By taking over the total work of breathing and allowing the patient to rest, it decreases the metabolic rate and oxygen consumption.
2. The ventilator may provide a more even distribution of ventilation. This is achieved by decreasing inspiratory flow rate and briefly sustaining pressure near peak-inspiratory volume.
3. Oxygenation is improved both by more efficient ventilation and by the increased oxygen tension of the inspired mixture.
4. Time is gained for medical therapy.

Sedation

In order that patients in pulmonary failure may breath with the respirator some type of sedation is necessary. Downes[12] recommends intravenous pentobarbital, 0.5-1.0 mgm/lb each three to six hours. Adams[14] advocates the use of 0.1 mgm of morphine per kilogram every four hours and does not hesitate to give relaxants to facilitate ventilation. Sedation may also be produced by inhalational anesthesia with diethyl ether or halothane. Bendixen[15] reported that 58 per cent of patients in status asthmaticus were improved by the administration of ether. Halothane anesthesia has given dramatic relief to some patients suffering asthma attacks.

Mucus plugs are an important, correctable cause of pulmonary failure in the asthmatic patient.[16,17] Bohrod[18] noted the omnipresence of plugs when he studied lungs of victims of status asthmaticus from two to 71 years of age. He stated: "The pathologic picture was remarkably constant. The gross appearance of the lungs leads to the inevitable conclusion that dyspnea, anoxia and death were the result of plugging the bronchi by thick tenacious mucus plugs."

The plugs appear for a number of reasons. These patients inhale a large volume of dry gas. The gas is humidified from the airway mucus which results in the mucus becoming tenacious and forming plugs. The formation of plugs is also facilitated by an inadequate fluid intake in patients who are working so hard to breathe. The administration of sympathomimetics also produces viscid secretions. These factors tend to cause secretions to be viscous and tenacious and require therapy aimed at liquefaction and removal.

Hydration

The inhaled gas should be properly humidified so as to render it saturated at body temperature. Adequate hydration is most essential in liquefying secretions. An estimate of the degree of dehydration can be made from the history, based on the amount of fluid intake, vomiting, urinary frequency, fever and weight change. Fluid therapy is most efficiently administered by the intravenous route.

Saline Lavage

Richards[10] and Logan[17] noted that when a nasotracheal tube is in place saline lavage of the respiratory tree has been used with success to remove secretions. This may be accomplished by injecting into the endotracheal tube 10 to 15 cc of saline warmed to body temperature, ventilating the patient two or three times, and then using an appropriately sized catheter to aspirate the returns by a sterile technique. Mist is an effective expectorant which prevents drying and facilitates liquefaction of secretions; appropriately sized mist particles may be delivered by the pressure breathing apparatus. Iodides may be useful as expectorants and are given intravenously as sodium iodide.[10]

Relieve Bronchospasm

Bronchospasm is an important correctable factor in the pulmonary failure of asthma. The narrow bronchi and bronchioles are a result of smooth muscle spasm. As the disease progresses, the narrowing of the airway becomes so severe that wheezing ceases, especially in children. This loss of wheezing is one of the ominous signs of pulmonary failure.

In patients with asthma the use of epinephrine or theophylline will usually improve aeration by relief of bronchiolar spasm. This does not often happen in status asthmaticus since these patients have become "epinephrine fast." Because these children do not respond they often receive large doses of sympathomimetics which cause symptoms of overdosage and make the pulmonary failure more severe.

Aminophylline is one of the most effective bronchodilating drugs and, for the treatment of intractable asthma, is usually given by the intravenous route. It directly relaxes the bronchoconstrictor muscles. Over-zealous treatment with aminophylline causes irritability, restlessness, convulsions and, finally, coma. Therefore aminophylline should be used sparingly—about 100 mgm for infants and 250 mgm for older children.[19]

Corticosteroids

Corticosteroids are useful in the management of status asthmaticus; the reduction in mucosal edema, inflammatory reaction, epithelial desquamation, and mucous gland activity may produce a dramatic improvement in airway obstruction. The dosage varies from 50 to 200 mgm of cortisone or its equivalent a day in four divided doses and depends more upon the severity of the disease than upon the age or weight of the patient.[20]

Correction of Metabolic Acidosis

Acidosis is an additional reversible factor which contributes to mortality in pulmonary failure in status asthmaticus. As arterial tension falls the tissues are forced to utilize anaerobic metabolism. Small elevations in lactic and pyruvic acid appear in the blood.[12] These and other organic acids produce an acidosis in over 75 per cent of pediatric patients in status asthmaticus.[21] The younger the patient the more severe the acidosis. Metabolic acidosis associated with pulmonary insufficiency in asthma has been under-emphasized, especially in the pediatric group. The metabolic acidosis results from inadequate caloric intake, marked exercise of respiratory muscles, excessive use of sympathomimetic amines, dehydration and hypoxia. The combined metabolic and respiratory acidosis progresses rapidly and, unless ventilation is augmented, circulatory depression and cardiac arrest will occur.

Cardiac depression is one of the severe consequences of acidosis. The rationale for the correction of arterial pH is based upon the improvement in systemic and coronary circulation which follows intravenous administration of sodium bicarbonate to acidotic experimental animals.[22] The resultant decreased resistance in the cardiac and systemic vascular beds improves tissue perfusion. Another consequence of acidosis is pulmonary vasoconstriction.[10] Liljestrand recently concluded that an increased hydrogen ion concentration in the blood is a chemical stimulus for pulmonary vasoconstriction.[23]

Acidosis also results in a less efficient transport of oxygen as a consequence of the "Bohr effect." When hemoglobin is acidotic the oxygen dissociation curve shifts to the right and a higher oxygen tension is required to achieve a given oxygen saturation in the blood. In a patient already hypoxemic the shift only intensifies tissue hypoxia.

At an acidotic pH, cellular oxidative enzymes function poorly because the mass action of CO_2 inhibits the decarboxylation process. Because of this the cells utilize anaerobic metabolic pathways and increase the lactate pyruvate ratio in the blood.[10] This intensifies the metabolic acidosis.

Perhaps the most important consequence of acidosis in pulmonary failure for the patient with asthma has to do with the action of sympathomimetic drugs. Bridget and Visscher[24] pointed out in 1927 that adrenaline works best in an alkaline medium. Blumenthal[25] stated that nothing was more disturbing in treating the asthmatic patient than to find that epinephrine, the best drug in treating an acute attack, was losing its effectiveness. He indicated that the decreasing arterial pH diminished the response to epinephrine and resulted in the so-called epinephrine-fast asthmatic.

The prevention of the consequences we have just described demands that acidosis be corrected. But when is it severe enough to need correction? Most workers[13,14,26] agree that if the pH is less than 7.20, then the factors discussed above are operating significantly.

Sodium bicarbonate and THAM* [Tris(hydroxymethyl)aminomethane] act directly and rapidly in correcting acidosis. Sodium bicarbonate binds the H^+ with its HCO_3 radical and displaces the reaction $CO_2 + H_2O \longleftrightarrow H_2CO_3 \longleftrightarrow H^+ \; CO\text{-}_3$ to the left by generating more H_2CO_3 and more CO_2.[12] The THAM buffer might appear preferable in status asthmaticus since its buffering action is not dependent upon the excretion of carbon dioxide. THAM binds H^+ with its amine radicle and decreases carbon dioxide concentration by displacing the reaction to the right. If renal function is adequate the resultant bound H^+ is rapidly excreted. THAM is not without hazard, however, as it may produce respiratory depression and should not be administered unless ventilation may be assisted. Because THAM produces a stronger alkalizing effect than other agents, frequent determinations of acid base variables must be obtained.

It is often difficult to determine the amount of alkalizing required. If the apparatus used to determine blood gases is an Astrup unit, the Siggaard-Anderson nomogram will give the base excess (B. E.).[27] A negative base excess means that a basic deficit exists and more base is required. The formula that can be used is millimoles of THAM = – base excess (mEq./L) x body weight (K) x 0.3. The factor 0.3 takes into account the volume of extracellular fluid (assumed to be 20 per cent of body weight) and the unionized fraction of tris (30 per cent at pH 7.40).[28] In most instances a 0.3M solution of THAM, an isosmotic solution with body fluids, should be used. Then the formula is simplified to:

$$\begin{aligned}\text{ml of 0.3M THAM} &= -\text{base excess x body wt (Kg) x } 0.3 \times 3.33\\ &= -\text{base excess x body wt (Kg)}\\ &\qquad (\text{mEq/L})\end{aligned}$$

THAM comes in an ampule of 36 grams. When mixed with 1000 cc of diluent, a 0.3M solution results. While the solution is being prepared, sodium bicarbonate may be given to correct the acidosis. This may be administered as rapidly as 9 mEq per minute.[10] A useful formula for bicarbonate dosage is:

$$NaHCO_3 \text{ (mEq)} = \frac{\text{body weight (kg)}}{5} (-BE).$$

Correction of Respiratory Acidosis

Mechanical ventilators are the most effective method of managing respiratory acidosis in children with status asthmaticus.[8,13,21] The choice of respirator is dictated by availability, the familiarity of the therapeutic team with the machine and the special requirement of the patient. The measurement of expired minute ventilation by a respirometer at the time of arterial sampling is necessary to monitor therapy. The aim should be to remove CO_2 over a period of several hours, but no faster than 10 mm Hg carbon dioxide tension per hour. Unless carbon dioxide is removed slowly seizures and shock may occur.[29] If therapy with the ventilator is to be effective secretions must be removed.

The most common cause of pulmonary failure in the pediatric asthmatic patients is a respiratory tract infection. When instituting therapy in these patients a culture and antibiotic sensitivity should be obtained so that the appropriate antibiotic may be begun if pathogens are present. If infection occurs during therapy prompt investigation and treatment is mandatory.

Cystic Fibrosis

In contrast to the pulmonary failure seen in status asthmaticus that of cystic fibrosis is almost completely a consequence of the unique viscid tracheobronchial secretions which account for most of the morbidity and 90 per cent of the mortality.[30] The primary pulmonary lesion of cystic fibrosis is partial bronchial obstruction by secretions.[31] The ciliary activity, expired air flow, and coughing which move normal mucus freely are ineffective in preventing the accumulation of the thick, viscid mucus of the disease.

---

*Tham is also called Tris, Tris buffer, Tris amino. Talatrol (Abbott) is the trade name of the medically available preparation.

Inhaled bacteria are deposited on the stagnant mucus and propagate to produce local infection. Infection increases obstruction and further impairs the clearance of secretions by producing mucosal edema, inflammation, and exudation of inflammatory debris into the mucus. In response to inflammation more secretions are produced, until the final result is a vicious cycle of accumulating secretions, airway obstruction, infection, infection causing more obstruction and increased secretion. The important point in therapy is that, although the early stage of the lesion is reversible, if infection persists, the ciliated pulmonary epithelium is destroyed and the resulting squamous metaplasia produces permanent impairment of the cleaning mechanism of the airway.[30] If extensive damage occurs, bronchiectasis, abscess formation and peribronchial fibrosis result. The lesions progress to obstructive emphysema and cystic bronchiectasis. The functional residual capacity increases while vital capacity diminishes; the end result is severely limited respiratory movements, poor aeration with increasing hypoxia and carbon dioxide retention.

The diagnosis of acute pulmonary failure in cystic fibrosis requires a high level of clinical suspicion and patient observation. If the clinical signs and symptoms of pulmonary insufficiency are present, laboratory confirmation is indicated.

The Management

The management of acute pulmonary decompensation must be aimed at ventilation and removal of secretions since the basic defect in the disease is unknown. The initial step in therapy requires establishing an airway to provide a pathway for the removal of the bronchial secretions which usually have caused the pulmonary failure. We prefer nasotracheal intubation to tracheotomy because the artificial airway is seldom maintained for more than 24 hours. When intubation has been accomplished one first removes the gross secretions causing the failure and sends a sample of these to the laboratory for bacterial culture and antibiotic sensitivity tests. Often the thorough cleansing of the airway is sufficient to produce a dramatic improvement in the patient's condition.

The Airway

Since the establishment of an artificial airway removes the patient's method of humidifying inhaled air, one must supply properly humidified gases to prevent further drying of the viscid secretions. Aerosol therapy of appropriately sized particles will aid liquefaction. Edema in the airway may be reduced by administering nebulized neosynephrine which, because of its rapid action on the mucosa and its few side reactions, is the vasoconstrictor of choice. In addition to systemic antibiotics the areas of local infection in the lungs may be treated by nebulizing a suitable antibiotic through the airway directly to the site of infection.

Liquefying Mucus

Webb reported on his experience with acetylcysteine, a relatively new agent that is effective in liquefying mucus. The action of this agent is due to its dissolution of the disulfide bonds found in mucus. The agent may be given via a nebulizer.

Bronchial Lavage

Cenzlaux[32] recently compared the relative benefits and hazards of bronchial lavage involving 10 per cent acetylcysteine with that utilizing sodium chloride solution in a similar group of patients. He found that patients whose airways were lavaged with acetylcysteine had an increased arterial carbon dioxide tension and a decreased arterial oxygen tension immediately after treatment; those treated with NaCl had no change in blood gases. He also found that, regardless of the agent, pulmonary functions were reduced for two or three days but, if the lavage was part of a complete therapeutic program, improved pulmonary function could be demonstrated two to six weeks after therapy.

Positive Pressure Breathing

Positive pressure breathing apparatus is useful in providing short term ventilation and in the administration of local antibiotics and other medications. Its prolonged use results in an increase in functional residual capacity and a reduction in vital capacity. It should therefore be used only for intermittent treatments lest it do irreparable damage to the patient.

Summary

The basic principle of therapy in managing the pulmonary failure of bronchial asthma and cystic fibrosis is to treat the potentially reversible features while providing support to correct the hypercapnea and hypoxemia. This requires a knowledge of the underlying disease, factors causing the pulmonary failure, and the correctable aspects of the crises.

Cardiac Complications of Chronic Pulmonary Disease in Childhood*

RUSSELL V. LUCAS, JR., M.D.†
Minneapolis, Minnesota

COR PULMONALE is the major cardiac complication of chronic pulmonary disease. As defined by a committee of the World Health Organization,[1] cor pulmonale is "right ventricular hypertrophy, secondary to disease of the lung parenchyma or pulmonary vasculature, or due to abnormalities of pulmonary function." Specifically excluded as causes are congenital heart disease and pulmonary hypertension secondary to disease of the left heart.

Physiology of Cor Pulmonale

Pulmonary hypertension is the basic underlying hemodynamic constituent of cor pulmonale. Knowledge of the mechanisms responsible for pulmonary hypertension in patients with chronic lung disease is central to our understanding of cor pulmonale. Pressure in the pulmonary artery is dependent on the resistance to blood flow imposed by the pulmonary vasculature. The pulmonary arteriole constitutes the major resistance vessel of the lung. Constriction of the pulmonary arteriole increases pulmonary vascular resistance and results in pulmonary hypertension.

Hypoxia and Hypercarbia

There are three factors common to patients with chronic lung disease which influence vasomotion of the pulmonary arteriole and thus pulmonary artery pressure.

Hypoxia (decreased arterial pO_2) alone has little effect on pulmonary pressure in normal man. Supportive evidence includes the many children with cyanotic congenital heart disease who have normal pulmonary artery pressure. Likewise, isolated hypercarbia (increased arterial pCO_2) has little effect on pulmonary artery pressure.

Acidosis

On the other hand, acidosis, either metabolic

Fig. 2—Schematic representation of auscultatory findings in cor pulmonale. At the cardiac base a systolic ejection click (SEC) immediately follows the first heart sound (S1). A systolic ejection murmur (SM1) is the result of turbulence as blood flows into the dilated pulmonary artery. The second or pulmonary component of the second heart sound (S2) is accentuated as a consequence of pulmonary hypertension. When pulmonary insufficiency is present an early blowing, decrescendo diastolic murmur (DM-1) is heard. When right ventricular dilatation is sufficient to produce tricuspid insufficiency, a holosystolic murmur (SM-2) and a mid-diastolic rumble (DM-2) are discerned at the apex. S3 = third heart sound.

or respiratory, significantly increases pulmonary artery pressure and appears to be the major regulator of pulmonary arteriolar vasomotion.[2] Furthermore, acidosis renders the pulmonary arteriole extremely sensitive to the vasocontrictor effects of hypoxia.

Figure 1 summarizes the "final common pathway" from chronic lung disease to right ventricular failure.

Diagnosis of Cor Pulmonale

A careful physical examination almost invariably allows the physician to make a diagnosis of cor pulmonale. The auscultatory features are depicted in Figure 2.

Pulmonary Hypertension

Pulmonary hypertension results in vigorous closure of the pulmonary valve. Since this valve is located in the anterior mediastinum in close proximity to the stethoscope, vigorous valve closure is easily detected as a *loud snapping second sound*. Accentuated pulmonic closure is best heard in the second, third, and fourth left intercostal spaces. Usually the second sound is not split widely and the splitting varies normally with respiration. Pulmonary hypertension also leads to dilatation of the main pulmonary artery. As a consequence of the disparity between the size of the pulmonary artery and the annulus of the pulmonary valve, turbulence is created as blood flows through the pulmonary outflow area, producing *a systolic ejection murmur*. The *systolic ejection click*, a sharp sound immediately following the first sound and heard along the lower left sternal border, is also commonly heard in patients with pulmonary hypertension. Pulmonary insufficiency is occasionally present in pulmonary hypertension and produces a *decrescendo early diastolic murmur* in the pulmonic area.

Right Ventricular Hypertrophy

The features of right ventricular hypertrophy include an accentuated right ventricular heave or lift which is maximal at the sternum. As the right ventricle dilates it creates enlargement of the tricuspid valve ring. The resultant tricuspid insufficiency produces a *holosystolic murmur* at the lower left sternal border and increases the amount of blood which must return from right atrium to right ventricle during diastole. The augmented diastolic flow produces the tricuspid flow murmur, a *mid-diastolic blowing murmur* heard best at the left sternal border in the fourth, third and second intercostal spaces.

Right Ventricular Failure

In addition to these signs of pulmonary hypertension and right ventricular hypertrophy, features of right ventricular failure are helpful when present. These include hepatomegaly, distended neck veins, peripheral edema and a prominent 3rd heart sound (systolic gallop rhythm).

Thoracic Roentgenogram

The most characteristic feature of the roentgenogram is enlargement of the pulmonary artery segment (Figure 3); the major pulmonary arteries are also enlarged. There is disparity between the accentuated proximal vascular markings and the normal distal vascular markings. Dilatation of the right ventricle and enlargement of the right atrium are observed in some patients.

Electrocardiogram

The electrocardiogram is variable in cor pulmonale because it is influenced not only by cardiac chamber enlargement, but by unusual positions of the heart in the chest, by changes in pulmonary volume, and by abnormalities of the thorax. Patients with chronic lung disease may have one or more of these factors.

The most helpful feature is electrocardiographic evidence of right atrial enlargement, which consists of tall peaked P waves (Figure 4). The tall P wave may be present in only one or in several of the following leads; I, II, III, AVL, AVF, VI and V2.

Electrocardiographic evidences of right ventricular hypertrophy are more variable since these may be masked by pulmonary and thoracic abnormalities. Right ventricular hypertrophy can be identified by the following features: upright T in leads V4R and V1 (between the ages of one week and eight years); and tall R in V_1 (greater than 20 millivolts) and/or a deep S in V6.

These physical and laboratory findings define the presence of pulmonary hypertension and the magnitude of right ventricular hypertrophy. Evidence of right ventricular failure indicates a severe degree of cor pulmonale and demands immediate and vigorous therapy.

Treatment

A review of the "final common pathway" (Figure 1) identifies the various areas to which treatment might be directed. Thus, we may attempt to improve the underlying pulmonary or thoracic disease, to correct hypoxia and/or acidosis, to alleviate pulmonary arteriolar constriction or to treat right ventricular failure.

Treatment of the underlying pulmonary or thoracic disease must be the primary goal and is the most effective. Treatment directed to the pulmonary problem must be vigorous, aggressive and continuing.

Oxygen

The goal of treatment is improvement of oxygenation while avoiding development or progression of respiratory acidosis (hypercarbia). Efforts at improving oxygenation may be successful for short periods, but ultimate

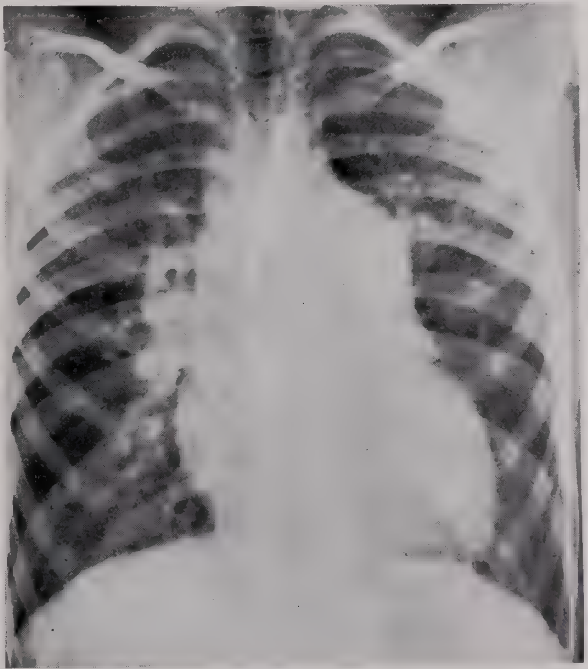

Fig. 3—Thoracic roentgenogram in a 10-year-old child with chronic cor pulmonale. Note the characteristic enlargement of the pulmonary artery segment. There is a disparity between the normal peripheral pulmonary markings and the prominent proximal hilar pulmonary vessels. The heart is not significantly enlarged. There is evidence of diffuse parenchymal lung disease.

success depends upon improvement in the underlying pulmonary disease.

Oxygen therapy in children with chronic lung disease must be approached with caution. Inhalation of oxygen in concentrations greater than 60% over a period of days is toxic in man and animals. However, a more important consideration in a patient with chronic lung disease is the frequent association of hypercarbia. When hypercarbia has been present the respiratory center may no longer respond to changes in pCO_2. In this situation hypoxia provides the drive for respiration. Inhaled oxygen, by alleviating hypoxia, thus removes the respiratory drive, allows a decrease in ventilation, and results in a rise in pCO_2 and in CO_2 narcosis. Prevention of CO_2 narcosis requires that oxygen therapy be combined with artificial ventilation; but oxygen therapy with or without positive pressure ventilation provides only a temporary respite: time which must be used to relieve the underlying lung disease.

Buffer Solutions

Acidosis alone produces pulmonary hypertension and in addition makes the pulmonary arteriole more sensitive to the vasoconstrictor effects of hypoxia. Acidosis may also be controlled for short periods of time with buffer solutions such as sodium bicarbonate or tris buffer. Administration of these agents must be carefully monitored with blood gas determinations.

Pulmonary Arteriolar Vasodilatation

While it is possible to dilate the pulmonary

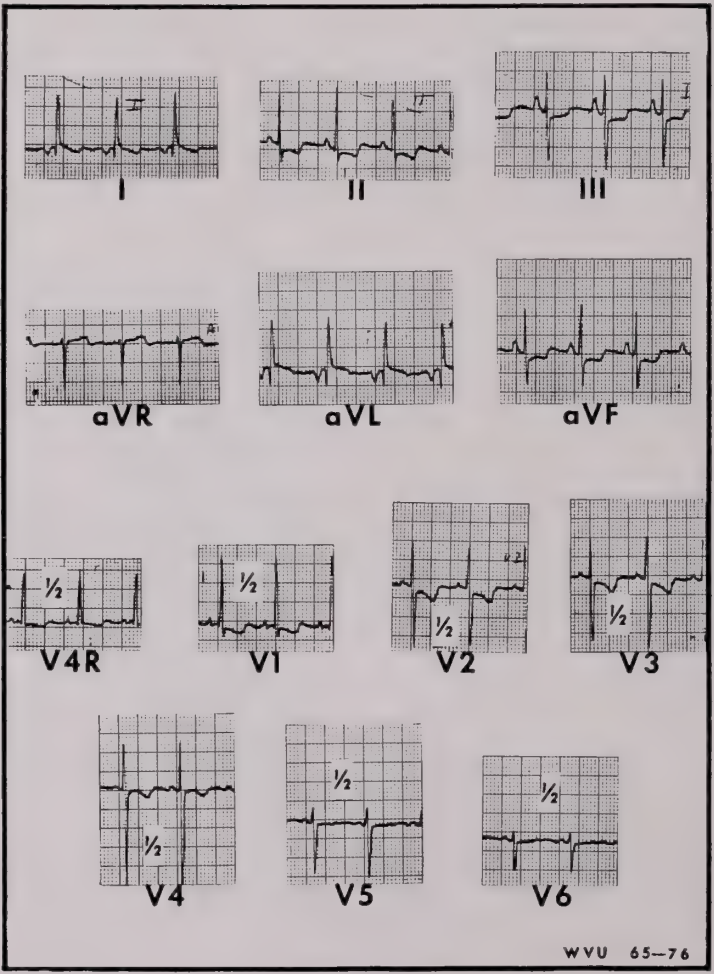

Fig. 4—The electrocardiogram in a five-year-old child with cor pulmonale. Right atrial enlargement is reflected by prominent peaked P waves in lead III only. The tall R waves in V4R and V1 and the deep S waves in V5 and V6 reflect pressure hypertrophy of the right ventricle. ½ = half standard.

arterioles with infusion of acetylcholine into the pulmonary artery or by the administration of isoproterenol or Priscaline,® the effects of these agents are short-lived and capricious and require continuous hemodynamic monitoring. They have not achieved clinical usefulness.

Improvement of Cardiac Function

Digitalization

Right ventricular failure dictates immediate efforts to improve cardiac function. Simultaneous efforts must be made to improve ventilation and oxygenation.

In our experience digoxin (Lanoxin®) is the most useful digitalis glycoside. Our dosage schedule is:

Total digitalizing dose (TDD) of digoxin (Lanoxin®)

Prematures and neonates (first 30 days)	0.035mg/k
One month to two years	0.05 mg/k
Over two years	0.035mg/k

One half of total digitalizing dose initially 1/4 in six hours, 1/4 in 12 hours, (I.M.). Maintenance to start 24 hours after first dose; 1/7 of total digitalizing dose bid. Owing to the variability of response to digoxin, patients must be monitored carefully and the dosage altered accordingly.

Diuresis

Diuretic therapy provides good short-term symptomatic relief until definitive therapy of the pulmonary problem is achieved.

Meralluride given intramuscularly is an effective, rapid-acting diuretic. Our dosage schedule is premature and neonate 0.1 ml; infant, 0.25 ml; 1-5 years, 0.5 ml; 5-12 years, 1.0 ml. This dose may be repeated daily for three days.

Intravenous ethacrynic acid is a potent diuretic for use in critical situations; but the electrolyte status must be determined before this drug is used, and the fluid and electrolyte balance carefully monitored after dosage, since salt and water loss may be massive.

The usual dosage of ethacrynic acid is 1 mg/k intravenously over a 10-minute period. This dose may be repeated in six hours, but only after measurement of the patient's fluid and electrolyte status.

Summary

Whatever the nature of the underlying pulmonary problem, the genesis of cor pulmonale can be represented by a "final common pathway" from acidosis and hypoxia to right ventricular failure.

An understanding of this pathway permits the diagnosis of cor pulmonale and provides the basis for rational therapy.

The sine qua non of treatment of cor pulmonale is improvement of pulmonary function. The purpose of therapy directed to the cardiac problems is to buy time which must be utilized in the vigorous treatment of the underlying pulmonary problem.

If all the neglected Bibles were dusted simultaneously, we would have a record dust storm and the sun would go into eclipse for a whole week.—David Nygren

WHAT'S
SO WEAK
ABOUT
THE WEAKER
SEX?

OFTEN...
HER LOWER
G. I. TRACT

Psycho-abdominal Distress: Frequently Female

Women aged 15 to 45 appear to be more prone than men to bloating, cramping pain of stress-related intestinal disturbances such as irritable or spastic colon.[1,2]

Frequently Recurrent

In the experience of many physicians, women are more likely to reappear time after time with repeated complaints of lower G.I. distress.

Requiring Definitive Therapy

Often needed is therapy adequate to control both the somatic and the emotional components of psycho-abdominal complaints.

Definitive Dual Therapy

'Milpath' contains a proven synthetic anticholinergic useful for relieving hypermotility, spasm, and hypersecretion of the gastrointestinal tract.

In addition, 'Milpath' provides a time-tested tranquilizer for mild but effective anti-anxiety action.

With Flexible Dosage

- 'Milpath'-400 (meprobamate 400 mg. + tridihexethyl chloride 25 mg.) Usual adult dose: 1 tablet *t.i.d.* and 2 at bedtime.
- **When less tranquilization is required: 'Milpath'-200 (meprobamate 200 mg. + tridihexethyl chloride 25 mg.)**

Wallace Pharmaceuticals/ Cranbury, N. J. 08512

gently but firmly

MILPATH®

(meprobamate + tridihexethyl chloride)

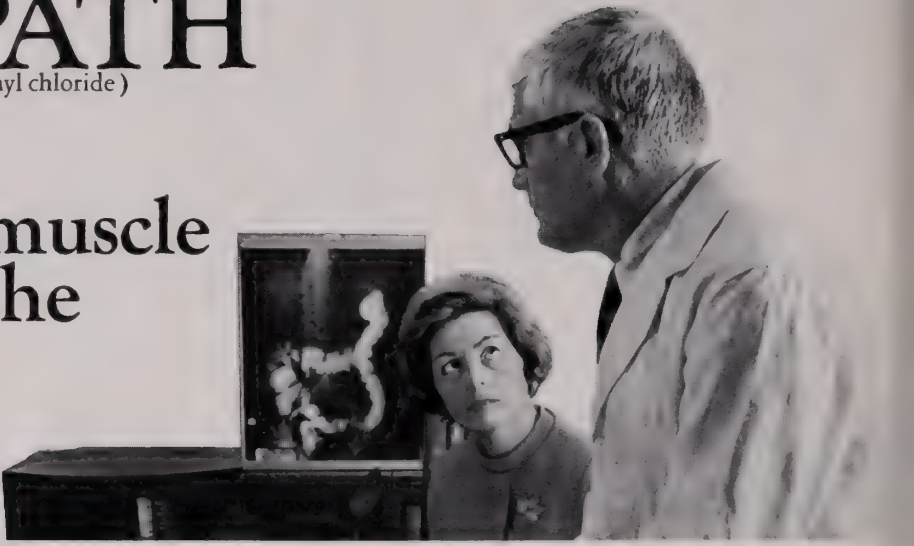
relaxes smooth muscle and psyche

Please see the following page for brief summary of prescribing information.

Gently but firmly MILPATH®

(meprobamate + tridihexethyl chloride)

Relaxes smooth muscle and psyche



Usual Adult Dosage

One 'Milpath'-400 tablet, three times a day at mealtimes, and two at bedtime. For greater anticholinergic effect, two 'Milpath'-200 tablets, three times a day at mealtimes and two at bedtime. Doses of meprobamate above 2400 mg. daily not recommended.

Indications

Useful in organic and functional disorders with hypersecretion and hypermotility of G.I. tract, especially when accompanied by anxiety, neurosis, or tension states. Should be used as an adjunct to all other therapeutic measures.

Contraindications

Tridihexethyl chloride: Urinary bladder-neck obstructions, e.g., prostatic obstruction due to hypertrophy; pyloric obstructions because of reduced motility and tonus: organic cardiospasm (megaesophagus); glaucoma; possibly in stenosing gastric or duodenal ulcers with significant gastric retention.

Meprobamate: Previous allergic or idiosyncratic reactions to meprobamate.

Precautions

Tridihexethyl chloride: Use cautiously in elderly males (possible prostatic hypertrophy).

Meprobamate: Carefully supervise dose and amounts prescribed. Consider possible dependence or habituation (reported occasionally after excessive use), particularly in severe psychoneurotics, alcoholics, ex-addicts. Withdraw gradually (one or two weeks) after excessive dosage for weeks or months to avoid recurrence of pre-existing symptoms (e.g., anxiety, anorexia, insomnia) or withdrawal reactions (e.g., vomiting, ataxia, tremors, muscle twitching; rarely, epileptiform seizures, more likely in those with CNS damage or latent convulsive disorders). If drowsiness or visual disturbance occurs, reduce dose and advise against activity requiring alertness (driving, machinery operation). Effects of excess alcohol may be increased. Grand mal seizures possible in persons with both petit and grand mal. Prescribe cautiously in small amounts to patients with suicidal tendencies. Prescribe with caution to patients with known sensitivity to compounds of similar chemical structure, e.g., carisoprodol.

Side Effects

The following side effects of components may occur with 'Milpath'.

Tridihexethyl chloride: Severe effects rare on recommended dosage. Anticholinergic effects: dry mouth (fairly frequent at oral doses of 100 mg.), constipation or "bloated" feeling. Possible: tachycardia, dilation of pupils, increased ocular tension, weakness, nausea, vomiting, headache, drowsiness, urinary hesitancy or retention, dizziness.

Meprobamate: Drowsiness, sometimes with ataxia, usually controlled by decreasing dosage, occasionally with aid of central stimulants (e.g., amphetamine). Rarely, allergic or idiosyncratic reactions (usually after one to four doses); in mild form: itchy, urticarial or erythematous, maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever, transient leukopenia, and one fatal bullous dermatitis (after meprobamate and prednisolone) reported. More severe, very rare hypersensitivity fever, chills, fainting spells, angioneurotic edema, bronchial spasms hypotensive crises (one fatal), anuria, anaphylaxis, stomatitis and proctitis. Treat symptomatically (e.g., epinephrine, antihistamines possibly hydrocortisone); stop and do not restart the drug. Isolated agranulocytosis, thrombocytopenic purpura, one fatal aplastic anemia reported, but only in presence of known toxic drugs, porphyric symptoms reported but relationship not established. Fas EEG activity, usually after excessive dosage. Impairment of visua accommodation reported by one observer. Fixed drug eruption with meprobamate and cross reaction to carisoprodol reported.

Suicidal attempts may produce drowsiness, lethargy, stupo ataxia, coma, shock, vasomotor and respiratory collapse, an death. Excessive dosage has led rapidly to sleep, then reduction o vital signs to basal levels. Empty stomach, and if respiration b comes very shallow and slow, cautiously give CNS stimulants (e. caffeine, pentylenetetrazol, amphetamine); also pressor amines i indicated.

Supplied

In two strengths:
'Milpath'-400: Yellow, scored tablets.
'Milpath'-200: Yellow, coated tablets.
Before prescribing, consult package circular.

Bacteria in the Sputum*

Pediatric Patients with Chronic Pulmonary Disease

PAUL G. QUIE, M.D.
Minneapolis, Minnesota

THE LOWER RESPIRATORY tract is normally sterile. This fact so easily stated is evidence of the remarkably capable host defense mechanism in the lungs. Bacteria are constantly present and are sometimes in high concentration in the air we breath. In spite of this, the magnificent defense mechanism of the lower respiratory tract keeps the lungs sterile. The upper respiratory tract, on the other hand, is never sterile and is simultaneously colonized by several bacterial species. There are poorly understood checks and balances among the different bacterial varieties and the host; but in health the so-called "normal flora," together with potential pathogens, live harmoniously together. As might be expected, there are symptoms of infection when particularly virulent outside bacterial invaders (such as group A streptococci) become the predominant organisms of the upper respiratory tract; but even during these illnesses the sterility of the lower respiratory tract is maintained.

These observations have led to postulation that bacterial invasion of the lower respiratory tract can take place only when there is a preceding non-bacterial injury which reduces the effectiveness of the host defense mechanisms. Traumatic injury to the anatomical barriers, virus injury of the cells of bronchi or alveoli, and obstruction to ciliary action are examples. Therefore, it is not surprising that the bacterial etiology of lower respiratory tract disease is usually a species such as pneumococcus which is typically present in the upper respiratory tract. Pneumococci are frequently recovered from the bronchial secretions of patients with chronic respiratory tract disease and may play a role in the continuing inflammatory response in these patients. This may seem paradoxical since pneumococci are frequently associated with acute pneumonia which is fatal or cured within a few days; however, there are more than 72 capsular types of pneumococci and only a few virulent or acute pneumonia-producing types. The pneumococcal types recovered from patients with chronic pulmonary disease are usually different from those in patients with acute pneumococcal pneumonia.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

Hemophilus Organisms

A similar situation exists with *Hemophilus influenzae*. Hemophilus organisms are also part of the normal flora of the upper respiratory tract, but these are usually non-encapsulated and therefore non-typable. The virulent hemophilus organisms recovered from patients with meningitis or osteomyelitis usually have capsules and are Type B. It must be emphasized here that the presence of pneumococci or hemophilus in lower respiratory tract secretions cannot be considered normal regardless of the type, and they undoubtedly contribute to inflammatory response in this location and should be treated.

There is no correlation between the potential pathogens recovered from cultures of the pharynx and carefully collected secretions from the lungs. Transcutaneous tracheal aspiration or bronchoscopy, therefore, is necessary for collection of pulmonary secretions for culturing.

Staphylococcus Aureus

Staphylococcus aureus is present in the upper respiratory tract of approximately 30% of nearly any population; however, it is an exceedingly infrequent organism in the lower respiratory tract of patients with chronic lung disease, except in those with cystic fibrosis. These patients almost uniformly harbor staphylococci in their bronchi, and the resulting inflammatory response leads to purulent bronchial secretions and eventual parenchymal fibrosis. The association of staphylococcal bronchitis and cystic fibrosis is not a result of immunologic inability, since cystic fibrosis patients uniformly demonstrate high titers of anti-staphylococcal antibodies and their leukocytes show normal ability to phagocytize and kill staphylococci. The basis for this association of pulmonary staphylococci and cystic fibrosis is not known at present, but continuing investigation may help in understanding this crucial relationship.

Concluding Comments

The finding of viable bacteria in a part of the body which is normally sterile serves as a strong stimulus for vigorous antibody therapy with bactericidal antibodies. This response is correct; patients with chronic pulmonary disease are improved by antibiotic therapy, but this alone is *not enough*. The persistence of bacterial products as well as live bacteria in the lower respiratory tract continually stimulates inflammatory responses with infiltration of phagocytic cells, granuloma formation and parenchymal fibrosis. It is necessary therefore that these products be removed. The scrupulous attention to bronchial toilet which characterizes present-day management of cystic fibrosis patients is equally as important as antibiotics in the treatment of the bacteria in the lungs of patients with chronic pulmonary disease.

Pathiatry

This particular cult is trade-marked. "It combines the best principles of spinal adjustment, traction, manipulation, deep massage, etc., administered by oneself. So simple and delightful as to become a part of the daily toilet. Done anywhere, at any time, while standing, even sitting; without appliance of any kind.*

Cystic Fibrosis*

Surgical Treatment of Pulmonary Complications

DOUGLAS S. HOLSCLAW, M.D.†
HARRY SHWACHMAN, M.D.†
Boston, Massachusetts

As a result of the medical management of infants and young children with the early pulmonary involvement of cystic fibrosis and because of the striking improvement in the surgical management of infants with meconium ileus, there are now a relatively large number of patients with cystic fibrosis who live well into their teens and beyond. Over 90% of all patients with cystic fibrosis show either clinical or x-ray evidence of pulmonary involvement, usually both.

Certain pulmonary complications, if left untreated, will lead to more rapid progression of the disease. Among these are lobar and lobular atelectasis, usually with underlying abscess formation and bronchiectasis; large lung abscess cavities; localized areas of bronchiectasis; lobar botryomycosis;‡ pneumothorax, and empyema. Because of this, we have encouraged palliative pulmonary resection in carefully selected patients.[1] By this, we hope to relieve some of the acute symptoms present and to slow progression of total pulmonary involvement as well. Pulmonary resection in this disease should be undertaken with the full understanding that pulmonary involvement is never limited only to a single segment of a lobe. When proposing resection to the parents of these patients it must be emphasized that this is only a palliative procedure.

Preoperative Evaluation and Management

All patients have been on a full medical program of antibiotics, physical therapy, mist tent, expectorants and usually antibiotic and mucolytic aerosol inhalations. In general, attempts to expand an atelectatic lobe or segment by bronchoscopy and suction have not been successful. We rarely employ bronchograms now

since many of our patients in the past have not tolerated bronchography well. We can now obtain much more information by the comparison of perfusion and ventilatory scans using either the Technetium^{99} labeled albumin microaggregate or Xenon^{133} techniques. In patients who are old enough to cooperate, pulmonary function tests have given a good prediction of the patient's postoperative pulmonary status. In almost all cases, the affected area of lung removed was not of functional value. In cases where an entire pneumonectomy is contemplated, we have utilized cardiac catheterization employing a balloon to occlude the pulmonary artery on the affected side to determine if the remaining lung can withstand the increase in pulmonary blood flow. Differential bronchospirometry may be an additional useful tool when pneumonectomy is being contemplated.

TABLE 2

Pulmonary Resection in 38 Patients with Cystic Fibrosis

Right Side		Left Side

TABLE 3

Results of Pulmonary Resections

Excellent	3 (8%)	Symptom-free with full activity
Good	21 (54%)	Definite decrease in symptoms with increased sense of well-being
Fair	6 (16%)	Mild decrease in symptoms with increased sense of well-being
Unsatisfactory	2 (6%)	Unchanged
Poor	6 (16%)	Patient either died as result of operation or is worse.

The patient is brought into the hospital about one week prior to surgery to ensure psychological adjustment to his surroundings and to facilitate vigorous pulmonary toilet. We strongly urge that a tracheostomy be performed some four to six days prior to the thoracotomy. In this manner, the child can adjust somewhat to a new way of breathing, talking and coughing, and the vigorous suctioning that will be necessary in the postoperative period.

Surgical Considerations

Intubation and Operation

Our standard procedure is to carefully intubate the opposite bronchus with a cuffed tube after a vigorous initial suctioning of all areas of the bronchial tree; this minimizes the spillover of contaminated secretions into less involved areas of the lungs. The patient is then placed in the face-down position and the thoracotomy and resection follow in a routine manner. There is usually a shortening of the bronchi as a result of the chronic inflammation present as well as increased vascularity and a proliferation of large perihilar and peribronchial lymph nodes.

Postoperative Management

To date 88 episodes have occurred in 46 patients.[2] Large doses of intravenous antibiotics are used, and early ambulation and introduction of physical therapy are urged. We do not recommend the use of intermittent positive pressure

apparatus.

Pneumothorax

The majority of the patients with this pulmonary complication were treated by tube thoracotomy. This is usually done under local anesthesia if the patient is at all cooperative. Underwater seal and suction is used until there is no further evidence of air leakage and the lung is expanded as indicated by x-ray. The chest tube is then clamped for a 48-hour period and then removed if the lung continues expanded.

Our initial choice of treatment has depended on the clinical status of the patient and the degree of lung collapse (Table 1). Two patients expired before any treatment could be instituted, the pneumothoraces having occurred as terminal events. In 26 patients who had minor degrees of pneumothorax, no treatment was undertaken other than rest and observation. Four of these expired during hospitalization. In all the surviving cases the involved lung reexpanded. Six patients were initially followed by rest and observation alone, but soon required additional treatment due to increase in size of the pneumothorax. For 32 episodes, patients were treated with a single thoracostomy. An additional 15 cases were initially treated with a single chest tube, but further procedures were required for complications which ensued. Five patients were initially treated with thoracentesis, but four of these later required further procedures for re-accumulations of pleural air.

None of the cases have been treated with an open thoracotomy and stripping of the pleural surface. This is a subject to which we are giving considerable thought. In view of the high percentage of recurrences, it may prove advisable in certain selected patients to obliterate the pleural space and thereby prevent any future collapse.

A drawback of underwater seal suction and drainage is that the patient is relatively immobilized and thus at risk for accumulation of bronchial secretions. For milder degrees of pneumothorax and where there is no additional fluid to be removed, we are contemplating the use of the Heimlich one-way flutter valve.[3] This valve, which is attached to the end of the intrathoracic catheter, requires no suction, the air being expelled by the force of the patient's cough and forced increase of intrapleural pressure. The obvious advantage is that the patient can be fully ambulatory at all times.

Empyema

The standard surgical treatment for this complication is tube thoracotomy and drainage. Hopefully, this can be done without rib resection. Fortunately, empyema has become much less frequent in recent years, most likely because of early and massive antibiotic therapy for acute pulmonary infections.

Hemoptysis

Massive hemoptysis is occurring more frequently.[4] To date, we have not employed surgical intervention as the definitive means of controlling hemostasis. It is our opinion that the areas of bronchiectasis, from which the bleeding originates, have been too numerous and diffuse for resection. An additional difficulty has been the inability to precisely localize the site, not just the site of the bleeding. However, in view of the high mortality involved with massive hemoptysis, a more aggressive surgical approach may be justified in certain selected cases.

Results

Table 2 shows the findings in the 38 patients with cystic fibrosis who have been treated surgically. It is interesting to note that there were more than twice as many resections on the right side as on the left. The right upper and middle lobes were far more often involved than the lower. Since this does not hold true on the left side, it has been said that this distribution of localized atelectasis is reminiscent of the pattern likely to be seen in aspiration disease of the lung. In four of the 39 resections in these 38 patients, the underlying cause for the atelectasis was found to be botryomycosis. In five cases the atelectasis and bronchiectasis were so extensive that total pneumonectomy was required.

The results obtained in this group (Table 3) indicate that worthwhile palliation is possible in carefully selected patients. Twenty-four (62%) of the patients in this series obtained a good or excellent result. Eight (22%) had a poor or unsatisfactory result; in retrospect this was largely due to poor patient selection for surgery.

Conclusion

In the past, pulmonary surgery was felt by most to be contraindicated in this disease. We have shown by the above experience that there is a definite place for surgery in selected individuals. At present, such surgery is entirely palliative. The time may come when organ transplantation procedures will be well-enough developed so that lung replacement may be possible.

Acknowledgment

The majority of the operative procedures included in this report were performed by Dr. Samuel R. Schuster of our surgical staff.

Diabetes Kills

In a recent study conducted at Joslin Clinic, Boston, the average duration of life after the onset of diabetes in the young was reported to be less than 30 years! The latter part of these years is usually associated with blindness, hypertension, renal failure and other serious disabling complications. Diabetes affects more than 70,000 Minnesotans. It is the third leading cause of blindness, and the seventh cause of death in the United States.

Diabetes cannot currently be cured but can be controlled. Optimal control, however, can be carried out only by a well-informed cooperative patient working closely with an interested physician.

Education is a vital part of medical care for a patient with diabetes and his family. Minnesota is fortunate in having an area resource center which can provide extensive patient and family education. The Diabetes Detection and Education Center is a unique program supported by the U.S. Public Health Community Health Grant and the Northlands Regional Medical Program. Physicians in this region can refer patients to the Center for a five-day (40 hour) intensive educational program in diabetes and its management. A minimal tuition is charged and a complete report is returned to the referring physician. If long-term complications associated with this disease are to be minimized and hopefully eliminated, then optimal control by informed patients must be initiated at the onset of the disease. It is hoped that the Diabetes Center can assist the practicing physicians in initiating this form of quality medical care. Further information regarding the program or patient registration may be acquired by writing or phoning the Diabetes Detection and Education Center, 916 East 15th Street, Minneapolis, Minnesota 55404. A man of sixty has spent twenty years in bed and over three years in eating.— Arnold Bennett

Cystic Fibrosis[*]

A New Challenge to Internal Medicine

RICHARD E. POGUE, Ph.D.[†]
Augusta, Georgia
WARREN J. WARWICK, M.D.[‡]
Minneapolis, Minnesota

In recent years curiosity concerning the natural history of cystic fibrosis has led to several analyses of the survival of patients with that disease. With the accumulation of data through a nation-wide data collection system and a research grant sponsored by the National Cystic Fibrosis Research Foundation, we have disclosed marked improvements in the survival of these patients. We can now predict that over one third of the patients with cystic fibrosis, who are receiving treatment at a Cystic Fibrosis Center, will survive to receive care from the physician who practices internal medicine. These data also indicate that, at present, patients with cystic fibrosis who reach age 20 have a significantly higher mortality rate than younger patients.

Survival Curves

Prior to 1939

The Figure illustrates survival curves of patients with cystic fibrosis who have received various types of therapy.[1] The curve labeled "pre-1939 cases" is a survival cure for all reported patients with cystic fibrosis diagnosed prior to 1938. The high mortality in the first year of life is clear, retrospective confirmation of the clinical impression of the early 1940s that cystic fibrosis was a fatal disease of infants.

Minnesota Curve before 1963

The curve labeled "Minnesota before 1963" is representative of half a dozen curves obtained from patients diagnosed and treated for cystic fibrosis prior to 1966. The patients in these groups received antibiotic therapy plus general supportive measures—vitamins, pancreatic enzymes, expectorants and anabolic agents. We have interpreted the improved survival to indicate that the survival of children with cystic fibrosis is significantly improved

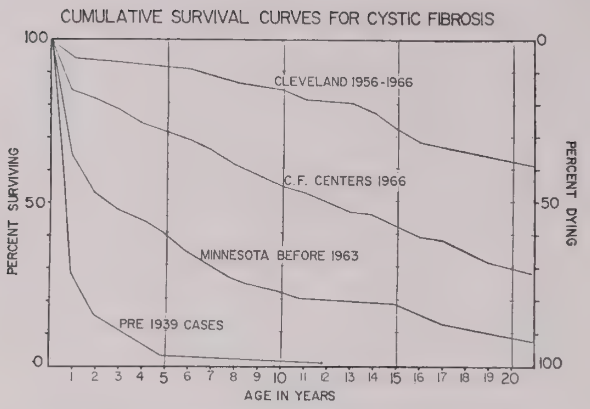
[‡] Associate Professor, Department of Pediatrics, University of Minnesota, Minneapolis, Minnesota.



Figure—Life expectancy curves for the natural course of cystic fibrosis and the improved prognosis with antibiotics are compared to mist tent, face mask aerosol and physical therapy drainage. The curve for patients cared for in cystic fibrosis centers and cystic fibrosis clinics in 1966 is based on 4,048 patients who received all types of pulmonary therapy plus antibiotics and other medicines. The curve for Cleveland is based on prophylactic pulmonary therapy approach developed at Western Reserve University by Matthews and Doershuk.

when the infectious pulmonary complications are treated.

Cystic Fibrosis Centers 1966

The third curve labeled "C.F. Centers 1966" represents the survival for 4048 patients with cystic fibrosis seen in 1966 at thirty-six cystic fibrosis centers throughout the country. These patients received the same supportive therapy given to the patients treated in the second curve plus various types of pulmonary therapy, including aerosol by face mask and mist tent and physical therapy to remove secretions from the lungs. The method of prescription of these treatments varied considerably from one center to another. At some centers these pulmonary treatments were reserved for patients who had severe disease, at others for patients who had any pulmonary disease, and at a few for all patients whether or not they had pulmonary

*Unweighted average age specific mortality rates.

disease. We have interpreted this improved survival as the direct result of the improvement in care which can be given by a physician who is knowledgeable in the disease and its complications and who adds the elements of pulmonary cleansing to the treatment program.

Cleveland 1956-1966

The fourth curve, "Cleveland 1956-1966," is data obtained from the Cystic Fibrosis Center at Case-Western Reserve University. All the patients at this center have been given the elements of therapy mentioned above, but the therapy has been used continuously from the time of diagnosis. This curve shows further significant improvement in the survival. We have interpreted this to indicate that the pulmonary complications of cystic fibrosis which lead to morbidity and death can be prevented or delayed by the early application of prophylactic pulmonary therapy.[2]

In comparing the curves we note four important findings: First, the period of greatest mortality is in the first year of life. Second, the more elements of therapy and the more intensely they are used, the greater the decrease in the first year of mortality. Third, the slope of the curve at the 50-percent survival decreases simultaneously with the availability of more techniques for therapy and with the great intensity in which these treatments are applied.

Fourth, in the curve with best survival, the slope increases as the age of the patient group increases, indicating an accelerated mortality with advancing age.

Mortality Related to Age

In Table 1 are recorded the age-specific mortality rates for patients with cystic fibrosis being treated at cystic fibrosis centers in 1964, 66, and 67. These data are based on all reported patients and include male and female patients unselected for birth complications. The data

TABLE 2

Age Specific Mortality Rates for Male and Female Patients Seen in 1966 and 1967

Year of life	All patients		Male		Female		Age period
0-1	.1176		.1153		.1199		Infancy
1-2	.0256	—.0438*	.0383	—.0347*	.0133	—.0528*	Pre school
2-3	.0454		.0190		.0703		
3-4	.0397		.0280		.0513		
4-5	.0539		.0384		.0692		
5-6	.0449		.0296		.0605		
6-7	.0536		.0549		.0523		
7-8	.0688	—.0656*	.0464	—.0565*	.0941	—.0737*	Primary

24-25	.2500		.1818		.4000		

*Unweighted average age specific mortality rates.

have been divided into five age periods.

Infancy

The first year of life because of the high infant mortality.

Preschool

The next six years of life, essentially the preschool period, during which an age specific mortality rate over 5 percent was observed only once. During this period the unweighted average age specific mortality rates for each of the years are close to 4 percent.

Primary

The six years of primary school during which we see a slight increase in the unweighted average age specific mortality to 6 percent per year.

Secondary

The six years corresponding to the junior and senior high school years during which the unweighted average age specific mortality rates underwent no essential change.

Post High School

The six years post high school encompasses ages 19 through 24. In a sense these patients are "on their own" and appear to do poorly. The unweighted average age specific mortality rates calculated for these years are two to three times greater than the rates of the previous two periods.

Mortality Related to Age and Sex

Table 2 contains the summarized data for the years 1966 and 1967, all patients seen, all males and all females. The five age periods are again used for comparing the survival of the males and females. This Table suggests that the male with cystic fibrosis has a survival advantage over the female. In the first year of life the evidence is slight, as the mortality rate for males is only slightly lower than for females. The rates are based on reports of 342 males and 353 females.

In each of the next three age periods, the preschool, the primary and the high-school periods, the mortality of the females is about 50 percent higher than the males. However, in the post-high-school period, the female mortality is 300 percent greater.

These mortality rates can be compared to a "base line," the preschool mortality, where we see a slight increment in mortality rates through each of the age periods: for males from 3½ to 5½ to 6% and then to 10%, a three-fold increase from the preschool to the post-high.

In contrast, for the females we find increments from 5 to 7 to 8 and then to 30 percent, a six-fold increase in mortality from the preschool to the post-high-school period and a three-and-one-half-fold increase in mortality from the high-school to the post-high-school period.

Discussion

The age-related increment in mortality from cystic fibrosis defies complete explanation. Nevertheless, we must analyze the possibilities so that we can attempt to change the course of these patients.

One obvious explanation is that these patients lived their early years prior to the general use of pulmonary therapies and, therefore, acquired such severe lung disease that these deaths in young adult life were ordained and predictable. Insofar as this is true, prompt diagnosis and treatment are the only measures available for amelioration of this trend.

Some age-related change in therapy could be contributory, e.g., separation from the home, loss of Crippled Children Services support for drugs and medical expenses, change of physician, changes in attitude towards life, e.g., failure to obtain employment, fear of losing employment because of illness, symptoms of illness, loss of time while visiting the doctor, inadequacies concerning marriage and raising a family, problems of earning enough to pay for medical expenses and still enjoy the fruits of their labors.

Whatever the reasons are for any individual young adult patient, all these reasons are important for the group. Every physician who supervises the health care of a young adult with cystic fibrosis should be aware that such multiple problems can adversely affect his patient; he ought to be sure in his knowledge of cystic fibrosis therapy through experience at a cystic fibrosis center; he must also analyze his patient's social, emotional, economic as well as medical problem and enlist by consultation or referral appropriate paramedical and social agencies and businesses to resolve these problems.

When the Brain Sleeps

An amazing thing took place on the Leningrad Front during the war. In May 1943 a wounded soldier in a very grave condition was brought to a field hospital. He was instantly put on the operating table. The operation began. Just then his blood pressure dropped dangerously. And the surgeon decided to make a blood transfusion there and then, while the operation continued. But it turned out that the conserved blood of the desired second group had all been used up, and two of the doctors instantly gave their own blood. Their blood was also of the second group. Three hundred and fifty cc were taken from each doctor, and the resultant total of 700 cc, a very big dose for a single transfusion, was immediately transfused to the wounded soldier.

Both the operation and transfusion were successful. There were no complications. The patient was making good progress. A few days later his condition was wholly satisfactory, and he was to be evacuated to the rear. But he looked pale and anemic, and the doctors decided to make one more blood transfusion. They took a blood test to make sure of his group, this being laid down by the regulations for each transfusion, and were aghast with the result. They could not believe their eyes. The soldier, it developed, belonged to the third-blood group, and not the second. Yet on the operating table no less than 700 grams of second-group blood had been transfused into him.

Seven hundred grams of second-group blood is certain death to a man with third-group blood. It is not surprising, therefore, that the doctors were utterly confused. The patient had not suffered any discomforts. On the contrary, the transfusion was followed by a marked improvement. For some reason incompatible blood had produced good results.

In 1943 the surgeons at the field hospital could not understand this phenomenon. But in 1944 it began to make sense. The remarkable and unexpected findings of Professor Galkin, a Leningrad patho-physiologist, and his associates shed light on the case when they discovered an amazing phenomenon: Many properties of the organism undergo great changes under the effects of narcotic sleep. Anesthetized cells can live under conditions that would be fatal to them under ordinary circumstances*

Social Stigmata of Cystic Fibrosis*

PAUL R. PATTERSON, M.D.†
Albany, New York

INHERENT IN THE physician is the desire to heal and restore his patients to normalcy. Often the medication that one prescribes becomes a magic potion to relieve the doctor's anxiety as much as to provide therapy for the patient. Because the emotional need of the physician is normally met by those acute medical and surgical problems which respond to immediate treatment, it is understandable that the failure of a patient with a chronic disease to respond and to recover engenders frustration and even annoyance. As a result, very few physicians find themselves attracted to treating chronic and prolonged illnesses, let alone those which can never be cured.

Likewise the relatives and parents of a chronically ill child find themselves annoyed, fatigued, and emotionally exhausted by the demands placed upon them to alleviate the illness. "Doctor, surely you or we can do something" is a plea that often expresses the sharing of the physician's inability to produce a cure.

The public renders sympathy and compassion for a crippling or chronic disease where a limp, a crutch or a brace is the symbol of an illness. The understanding that the patient and relatives receive from others observing such a handicapped child alleviates to some degree the burden by partial identification with the patient. But a child handicapped by a chronic disease which lacks such symbols receives very little empathy from the general public. In the case of cystic fibrosis the unglamorous association of foul-smelling stools, thinness, chronic cough and even disgusting purulent sputum produces a certain amount of annoyance or even loathing.

The empathetic pediatrician has learned that when a child has a prolonged illness which will result eventually in death and is accompanied by suffering for both the patient and the parents, a time arrives when the parents, exhausted by the medical treatment and the heroics, accept the inevitable death more realistically. Frequently the child recovers sufficiently to be discharged from the hospital to return home to await the next exacerbation of the disease. A point is finally reached in which the remissions may understandably be almost resented by the parents, for it is only normal that they should look forward to the relief of the patient's suffering by death. It takes a brave and intelligent parent to say openly, "I hope that my child does not suffer too much longer," and to realize that he may be expressing his own desire to be relieved of "chronic sorrow." I would suspect that the clergy and the physician, by not comprehending or recognizing the unspoken wish, are creating more guilt than is society by its silent censure.

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Albany Medical College of Union University, Albany, New York.

While we of the medical team must not give artificial hope, we must recognize that it is our duty as skilled, specialized pediatricians to produce a remission and restore the child to relative normalcy of living. We all have seen young adolescent cystic fibrosis patients who many years previously we had felt had but a few months to live. When one considers the medical and lay anticipation of a miracle to be found in a cure for such an entity as leukemia in childhood, where intensive therapy and hope is extended for a period of six to twelve months, we should be mindful of the years we have in our favor to reach ultimate control of cystic fibrosis.

The interpersonal relationships of a small child with cystic fibrosis may be perfectly normal when the child has been followed in a suitable clinic or center and is receiving the optimum therapy without incapacitation. However, when the condition has so progressed as to disallow normal exercise and social group activities, nothing is sadder to observe than the loneliness of a child looking out from the inside of a home at other children laughing, running and playing.

As the child with chronic lung disease such as cystic fibrosis reaches adolescence the innate desire to rebel and flee from parental supervision and to become like his peer group is an instinctual drive. The adolescent does not want to be different from his peers but does want to be different from "the older generation." For the first time, parents may be aware that their young child is now ashamed of his affliction and may literally deny his illness and offer excuses for the cough, the clubbed fingers, or the inability to participate in rugged dancing or sports.

When one recognizes the adolescent struggle for identity and acceptance both by himself and by others, one need not be a sympathetic individual to recognize the added burden placed upon a chronically ill child. The third cause of death of fifteen-to-nineteen-year-old youths, especially boys, is suicide. These are youths who have not become social dropouts but rather life dropouts overwhelmed by the cynical hopelessness of living. It is understandable that the intelligent adolescent soon recognizes that he has an incurable disease and that either his siblings or other patients attending the same doctor's clinic have died from this illness. One can recognize the refusal of the adolescent to receive or give himself the necessary therapy, as a reaction to any of the many complex emotional adjustments required either within the family constellation or within the social group, or because of the hopelessness he may feel.

When this adolescent has conquered the trying periods of high school, rehabilitation programs, and/or college and is ready to obtain employment, he unfortunately may find the employer "does not wish to assume the risk of his employment." With the publicity and encouragement given to employers to hire the mentally and physically handicapped, many are anxious to hire such individuals as tokens of open acceptance by their personnel department; but there has been a marked delay in acceptance of cystic fibrotics. Many patients have found that they need to deny their disease in order to obtain employment. The insurance companies have been the target for alibis by personnel managers who say that employing cystic fibrosis individuals would raise the cost of their premiums and not meet the guide-lines set down by the insurance companies. Most of the insurance companies that the author has approached, however, have denied this. We are now at the point of requiring governmental decision and policy in this matter.

It has been the experience of the National Cystic Fibrosis Research Foundation that a clinic or center for the chronic pulmonary-diseased child needs to revolve around a dedicated, sympathetic pediatrician who is willing to serve as physician, confidant, social worker, psychiatrist, physiologist, and "Big Daddy" to the entire family of the child. It is dismaying and discouraging to note that many of the directors of clinics for handicapped children find their patients, their clinic and their efforts receiving so little acceptance by their hospital and school administration that they must fight for funds, space and understanding, just as the parents of these children have been doing for years.

On Prognosis

It appears to me a most excellent thing for the physician to cultivate Prognosis . . . He should observe thus in acute diseases: first, the countenance of the patient. if it be like those of persons in health, and more so, if like itself, for this is the best of all; whereas the most opposite to it is the worst, such as the following; a sharp nose, hollow eyes, collapsed temples; the ears cold, contracted, and their lobes turned out: the skin about the forehead being rough, distended, and parched; the color of the whole face being green, black, livid, or lead-colored. If the countenance be such at the commencement of the disease, and if this cannot be accounted for from the other symptoms, inquiry must be made whether the patient has long wanted sleep; whether his bowels have been very loose; and whether he has suffered from want of food; and if any of these causes be confessed to, the danger is to be reckoned so far less; and it becomes obvious, in the course of a day and a night, whether or not the appearance of the countenance proceeded from these causes. But if none of these be said to exist, and if the symptoms do not subside in the aforesaid time, it is to be known for certain that death is at hand.

And, also, if the disease be in a more advanced stage either on the third or fourth day, and the countenance be such, the same inquiries as formerly directed are to be made, and the other symptoms are to be noted, those in the whole countenance, those on the body, and those in the eyes; for if they shun light, or weep involuntarily, or squint, or if the one be less than the other, of if the white of them be red, livid, or has black veins in it; if there be a gum upon the eyes, if they are restless, protruding, or are become very hollow; and if the countenance be squalid and dark, or the color of the whole face be changed—all these are to be reckoned bad and fatal symptoms.

The physician should also observe the appearance of the eyes from below the eyelids in sleep; for when a portion of the white appears, owing to the eyelids not being closed together, and when this is not connected with diarrhoea or purgation from medicine, or when the patient does not sleep thus from habit, it is to be reckoned an unfavorable and very deadly symptom; but if the eyelid be contracted, livid, or pale, or also the lip, or nose, along with some of the other symptoms, one may know for certain that death is close at hand. It is a mortal symptom, also, when the lips are relaxed, pendent, cold, and blanched.*

The great republic of medicine knows and has known no national boundaries.—Osler

Psychiatric Aspects of Chronic Lung Disease*

JOHN DUFFY, M.D.†
JOANNE L. HANSEN, ACSW†
Minneapolis, Minnesota

EVERY PATIENT who visits a physician because he is ill is worried. This worry may institute a psychological regression in the patient which can vary from mild in a relatively well person to severe in a relatively disturbed person. This response to illness is an example of the general human response to external threat or disharmony with the environment. The physician's ability to understand how the anxiety associated with an illness affects the patient and to use this understanding in the medical management of a disease may be crucial.

One thing common to all patients is anxiety connected with the diagnosis of their condition. They cannot deny the threat of this illness, though they may try very hard to do so. Whatever conceptions or misconceptions they may have about what is necessary for treatment of their disease seem to increase their anxiety and tension. But what is important is that each of them reacts to the anxiety with ritual methods and attitudes. These behavior patterns have to be understood as part of the patient's personality. They represent his leading reactions to stress and are the result of a long history of adjustment. As he grows up with these constitutional endowments and environmental experiences, he learns to find ways to compromise between his need and wishes on the one hand and the prohibition against fulfilling them at any price and at every moment on the other. If these conflicts between impulses and control arrive at a certain equilibrium in the adjustment process, the results appear as personality traits. In times of increased conflicts, as under pressures of anxiety, personality characteristics increase in intensity, as they attempt to maintain the inner balance. The patient therefore becomes less manageable than under average life conditions. One must therefore ask not so much what one can request from the patient, but what can one do to help him overcome his emotional response so that he can accept his physician's recommendations.

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 19, 1968.

†Division of Child Psychiatry and Department of Social Service, University of Minnesota, Minneapolis, Minnesota.

Case History

The patient is a 27-year-old man who was diagnosed as having cystic fibrosis at five years of age. Until the last few years he struggled with the feeling that his major identity was as a medical wonder, "one in a million," a "remarkable case." These labels connoted no sense of value or worth to him, only a sense of isolation, difference and aloneness. In addition, the medical procedures and equipment needed to maintain his functioning were hinderances to his wish for a sense of wholeness and adequacy. His feeling of defectiveness was even more stressful in the social area, where he could never be as active or as skillful as his peers.

Development and maturation is difficult enough without the added burden of limited opportunity with which to explore, test, and evaluate one's effectiveness as a person.

As a youngster, the patient was watched over and guarded by adults who were oriented to the possibility of imminent death. He was usually avoided by peers and potential friends who would "take a step back" upon learning that he had a serious illness. Teachers from grade school through college were reluctant to make demands or encourage long-range tasks which might prove stressful or be abruptly terminated by death.

These attitudes of others toward illness and death were always difficult for him to deal with until he became better able to cope with his own. Rather than confront people and ask for clarification of their ideas about his situation, he would withdraw. He became hesitant to involve himself with others because of his anxieties about exposing his feelings regarding the implications of his grave medical problem.

Several times in his life he had felt that psychiatric help would be quite useful in learning to cope with, not only his medical problem, but the everyday problems of living as well. As a youngster, he would probably have benefited most from intervention directed toward helping his parents to deal with his anxieties and questions as well as their own, and to develop more appropriate expectations of achievement and activity.

Later in the patient's life he often wondered about seeking psychiatric aid by sorting out his feelings in an effort to become a more effective person, but this idea was as disconcerting to him as it is to most people. He was unsuccessful in pursuing this idea as he could not come to any decision as to what problem to seek help for. The medical problem was being effectively handled by his physician, and he was uncertain whether his vague depression and anxieties were appropriate to take to a psychiatrist.

Even when he was seen by a counselor in college, he found it difficult to describe his needs and guide the therapist toward his areas of discomfort. The therapist in turn tended to be more concerned about his illness, following the pattern of seeing him primarily as a sick person.

It was not until two years ago at University Hospitals that doctors helped him enlarge this self image of a seriously ill person to a man with a serious illness, a shift of attitude which proved successful in all areas of his life. Through the encouragement to broaden his horizons and to persevere in looking for a job, he found hope that he could be a useful human being.

He had graduated from college with a degree in art but had been unsuccessful in gaining employment in this area as well as in others. Interviewers had not asked for clarification of his medical status but had only to hear that he had a chronic illness to refuse his applications. With the support of his doctors and the staff of the Cystic Fibrosis Foundation, the patient continued to look for work without denying his illness and without completely giving up hope of employment. He was finally hired in a managerial capacity with a major music distribution and retail firm where his drive to succeed has carried him quite rapidly into additional areas of responsibility. In this position he has been able to use his artistic talents and his growing skill in working with others.

Comments

Having given up a death orientation and taken on a new commitment to living the patient also decided to marry. He recently married a nurse from University Hospitals whom he met two years ago while hospitalized there.

They have decided not to have their own children but will attempt to adopt some. The decision to marry and raise a family was not taken lightly by either him or his wife. They were aware that many people would consider it unrealistic; indeed a most painful illustration of this involved his mother-in-law. When they visited this woman she was quite open and warm in receiving him as a son-in-law, but as the visit wore on she became more honest about her anger: in their marrying there was, in her opinion, a very high probability of early widowhood for her daughter and early death for any children they might bring into the world. He allowed her to vent her ire, thereby tapping his own concern, and was then able calmly and non-defensively to explain their reasons for going ahead.

A new-found confidence and strength in dealing with himself and others has led to a much more rewarding life. He denies neither the threat of death nor the reality of being alive. The impact of his present commitment to living is best illustrated by a relative who recently remarked, "Why L——, I remember you when you were dying!"

Summary

Chronicity can not only become a way of life for a patient; it also has the ability to evoke many reactions from those who are associated with him or who provide necessary care and treatment. The word carries a gloomy connotation and probably should never be used in discussing illness with a patient, for the person who hears his illness described as chronic may consider it beyond hope or help. For this patient, the concept of chronic disease had significant psychologic and social ramifications.

These principles apply to decisions around dietary restrictions and various forms of rehabilitation connected with chronic lung diseases. Whatever measures have to be instituted, in terms of the various forms of rehabilitation connected with chronic lung diseases, the gain from understanding the patient's personality structure and his dominant, central emotional needs is considerable, since it will permit the physician to deal with the patient's problem in a more appropriate and positive form.

Shakespeare's Doctors

Cerimon

"'Tis known, I ever
Have studied physic, through which secret art,
By turning o'er authorities I have,
Together with my practice, made familiar
To me and to my aid the blest infusions
That dwell in vegetives, in metal stones;
And I can speak of the disturbances
That nature works, and of her cures; which doth give me
A more content in course of true delight
Than to be thirsty after tottering honor,
Or tie my treasure up in silken bags,
To please the fool and death." (Pericles III, 2)

Scornful of hollow prestige and venality, thus spoke Cerimon when his friends expressed surprise that he, a nobleman, should show an interest and some skill in medicine. While only an amateur rather than a certified physician, he fully qualifies as one of Shakespeare's doctors, acquitting himself as ably as any.

When a chest containing the "corpse" of Thaisa is cast ashore from a shipwreck off the coast of Ephesus and is opened, Cerimon immediately detects that the body within shows faint signs of life and sets about to revive it.

"For look how fresh she looks! Make a fire within:
Fetch hither all my boxes in my closet.
Death may usurp on nature many hours,
And yet the fire of life kindle again
The o'erpressed spirits.
The fire and cloths.
The music there!—I pray you, give her air." (Pericles III, 3)

Cerimon's arsenal consisted of warm packs, fresh air, stimulating music, and unidentified substances from his boxes, presumably stimulants.

When Thaisa finally stirs and murmurs, Cerimon orders her carried off to bed—to be watched over closely.

"Hush, my gentle neighbors!
Lend me your hands; to the next chamber bear her.
Get linen: now this matter must be looked to,
For her relapse is mortal. Come, come;
And Esculapius guide us!" (Pericles III, 3)

Subclinical Pulmonary Disease in Children*

An Exercise in "Subclinical" Logic

WILLIAM W. WARING, M.D.†
New Orleans, Louisiana

VERY LITTLE HAS been written about "subclinical pulmonary disease" in children. Nevertheless, that phrase directs the mind into new channels, some of which will be explored here. Perhaps a crude map of this Terra Incognita will emerge.

We should begin with the key word itself. "Subclinical" is one of those etymological horrors that combines words from two languages. "Sub," of course, is Latin and means "under," whereas "clinical" comes from the Greek ϰλινιϰσς or "bed." It is mildly ironic that the clinic is a patient-care area that almost never contains beds. Subclinical therefore means "under the bed," which suggests dust, last Sunday's *Times*, or a chamber pot. But is there a better word? Could one use "asymptomatic?" I think not, since one can be asymptomatic either with or without disease. Moreover, clinical diagnostic methodology may detect disease that is asymptomatic—that is without symptoms. We shall stick with "subclinical" and develop its meaning by usage, since its derivation is not helpful.

Most physicians use the term "subclinical" to mean that disease exists in a patient in the absence of both signs and symptoms. Since the organs in question here are the lungs, subclinical pulmonary disease would imply disease of the lungs in the absence of cough, chest pain, dyspnea, bronchial breath sounds, etc.

Pulmonary diseases can be divided into subheadings of acute and chronic, as exemplified by pneumococcal pneumonia and tuberculosis. Can one speak of subclinical *acute* pulmonary disease? Undoubtedly it exists, but, as a practical matter, one can question its importance. If a disease is progressing rapidly, it will soon surface and become "clinical." If it goes away, what difference does it make? Our concern here is clearly with subclinical *chronic* pulmonary disease.

---

*Supported by a Center Grant from the National Cystic Fibrosis Research Foundation.

Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†From the Section of Pulmonary Diseases, Department of Pediatrics, Tulane University School of Medicine, New Orleans.

A definition is badly needed of "chronic pulmonary disease." I shall not attempt one here but, like you, will be thinking of protracted diseases affecting the lungs of children—tuberculosis, cystic fibrosis, fungous infections, sarcoidosis, and many others, including asthma.

Set theory and the Venn diagram can be used to explore subclinical disease of children's lungs. In the use of such diagrams, one must start with a Universe. Our Universe is depicted as a rectangular figure (*A*) that encloses "all children." Within the Universe are well children, sick children, children with chronic pulmonary disease, children without chronic pulmonary disease—literally, all children. The Universe is in flux since it is constantly being expanded by birth and contracted by death and graduation to adulthood (*B*).

Within our rectangular Universe we can define a circular "set," that is, a group of children differing in some respect from all other children. Set I represents children seen more or less regularly by doctors (*C*). Obviously, those within the Universe and outside of the set are not being so examined.

Clinical Disease

We can define another set. Set II shall consist of children with clinical pulmonary disease (*D*). They cough, produce sputum or blood, run fever, flare their alae nasi, and do all those things that one classically associates with diseases of the lungs. The majority of these children would be seen by a doctor; therefore Set II is mostly inside of Set I. However, for any of a thousand reasons, some would not be seen by a doctor and thus are represented by the portion of Set II that falls outside of Set I.

"False" Subclinical Disease

Another set, Set III, can now be developed within the Universe. It can be called "false" subclinical disease, whereby we indicate a group of children with mild or subtle expressions of their pulmonary disease (*E*). This group might be easily missed by a rushed history or superficial physical examination. But it would be detected by careful history-taking techniques or quantitative approaches to the physical examination. If it is true that the physician himself has trouble recognizing false subclinical disease, so indeed will the parent. Perhaps the majority of these children will not be taken to the doctor's office. Therefore Set III will lie to a greater extent outside of Set I than will Set II.

"True" Subclinical Disease

There is still another group within the Universe that is composed of children with pulmonary disease with absolutely no sign or symptom of its presence. They are diagnosable by application of a test—a tuberculin or sweat test, for example. This Set IV overlaps Set I only to the extent that chance alone will bring its members to a doctor's office (*F*). Furthermore, children within this set will be identified by the physician only if he does the right screening test.

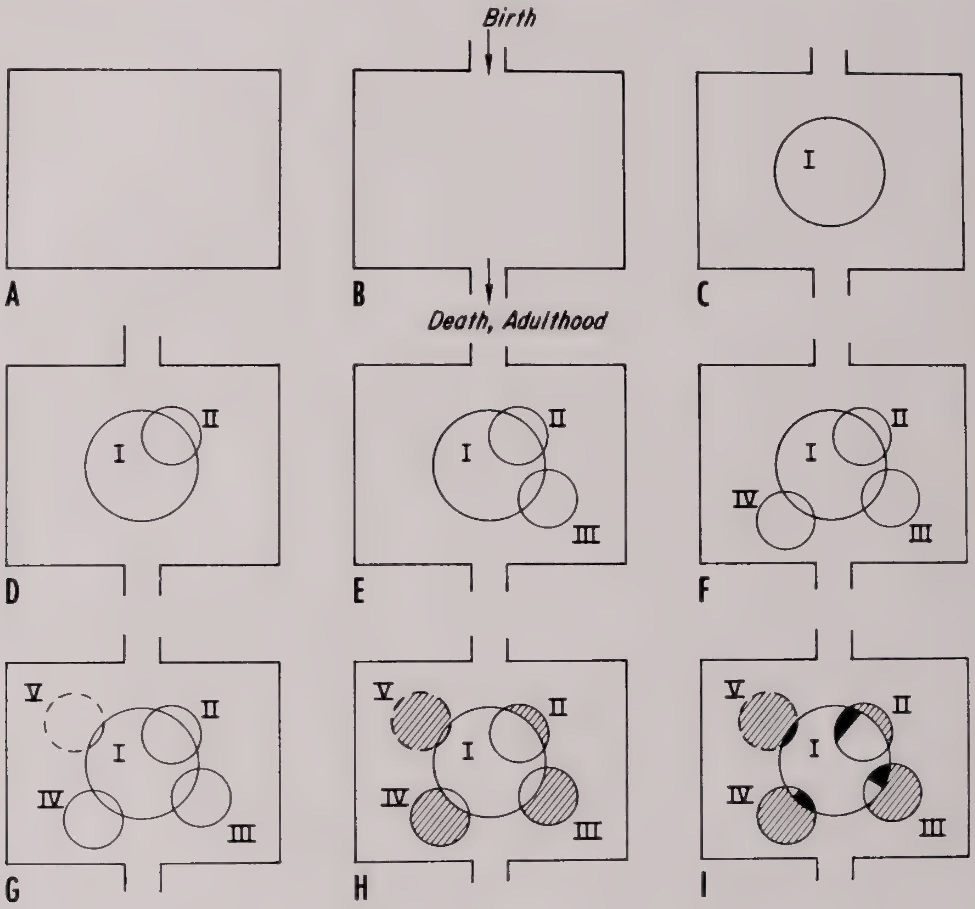
There is a last set, also of "true" subclinical disease, but in this case there exists no test that will identify its members. Set V, then, is undiagnosable true subclinical pulmonary disease. Its nebulosity is indicated by dotted lines (*G*), and its unidentifiable members float in the Universe and are seen by a physician for reasons other than their pulmonary disease. How do we know that such a set exists? It must exist. There is surely some molecular, biochemical, or biological deviation from normal that exists for a variable period in the natural history of any disease before conventional tests become positive and long before symptoms or signs appear. How does one diagnose primary pulmonary tuberculosis in the weeks between initial infection and the development of a cutaneous response to a tuberculin test? How does one recognize the "disease" produced in an asymptomatic adolescent cigarette smoker? Pulmonary function testing is scarcely the answer.

We have now diagrammed all possible categories of chronic pulmonary disease. It should be obvious that every child falling outside of Sets II through V does not have chronic pulmonary disease.

The relationship of the four disease sets to Set I is of interest. It is clear that, as disease becomes increasingly symptomatic, the chances of diagnosis are increased. The cloudiness of Set V, which has little in common with Set I, and the large overlap of Sets I and II represent the extremes of potential disease recognition by the physician.

The fully developed Venn diagram can now be used to define the children with pulmonary disease who will *not* be diagnosed. Clearly, those portions of each of the four disease sets that do not overlap Set I will not be recognized because the physician has no contact with the patient (*H*, shaded portions). But others will not be diagnosed either. Will a physician make an accurate diagnosis of every patient with obvious clinical disease? Humility and our own past experience tell us that some obvious diagnoses will be missed, even by competent clinicians. This percentage of missed diagnoses must increase as the difficulties of possible diagnosis increase. Ultimately, in no patients of Set V that the physician may see by chance will a correct diagnosis be made. Thus, even within his sphere of influence, the doctor will overlook children with chronic pulmonary disease (*I*, black portions).

Our Universe is in flux (*B*) due to children constantly both entering and leaving it. So too are the sets within the Universe. As a disease progresses, a child may move from Set V to



Figure

Venn diagram of clinical and subclinical chronic pulmonary disease. *A:* rectangle comprises *all* children (the Universe); *B:* the Universe is in flux, expanded by birth and contracted by death and adulthood; *C:* Set I comprises those children examined by a physician; *D:* Set II comprises those children with clinical pulmonary disease who may or may not be seen by a physician; *E:* Set III comprises those children with subtly expressed clinical pulmonary disease ("false" subclinical); *F:* Set IV comprises those children with no clinical expression of pulmonary disease, that is nevertheless detectable by application of the proper screening test (diagnosable "true" subclinical); *G:* Set V comprises those children with no clinical expression of pulmonary disease that is not presently detectable by any test (undiagnosable "true" sublinical); *H:* Analysis of types of pulmonary diseases that will not be recognized because of lack of exposure to the physician or to absence of a proper screening test (shaded portions of sets) and also because of diagnostic failure by the physician (black portions of sets). See text for further exposition of the diagram.

Set IV to Set III, standing more of a chance all the time of being one of those lucky individuals seen by a doctor who makes the correct diagnosis. It is also apparent that a self-limiting disease may be charted as retracing its steps back through the milder sets and finally into the pulmonary disease-free Universe.

The Venn diagram, as developed thus far, has been qualitative only—a model for consideration of diagnostic feasibilities. It shall remain qualitative here; but such a portrayal begs for quantitation in which the sizes of the sets would roughly portray the number of children represented by each. The Venn diagram would be different for each disease, depending on its incidence, symptomatic expression, and test-specificity. The spectrum of chronic pulmonary diseases then would consist of a spectrum of Venn diagrams, the area of whose black or shaded portions would indicate where diagnostic action must be taken. Therapeutic advances would be limited to the "white" portions of a diagram within Set I.

Efforts to increase the recognition of chronic pulmonary disease can be divided into those falling within Set I (the physician's sphere) and those outside of Set I (the community's sphere).

Improved Disease Recognition by the Physician

A physician can do little about those children with true subclinical disease for which no test is available. He can only await the discovery of new tests through the channel of basic and clinical research. Perhaps he can do more in the area of true subclinical disease for which tests are available (Set IV). Since the child is asymptomatic, the physician should apply certain screening tests to his entire patient population. The tuberculin test is a good example, since it is still not being universally and systematically used by physicians. Unfortunately, there is as yet no accurate screening test for cystic fibrosis that can be used in the doctor's office. Testing for cystic fibrosis is still being done only on patients in Sets II and III, although the future looks bright for such a test.

Every doctor should be interested in increasing his diagnostic efficiency in the areas of Sets II and III. Two of the purposes of a regional course such as this are to increase awareness and refine conventional diagnostic methods.

Certain non-specific screening tests are open to the physician. These include the chest x-ray, office pulmonary function testing, and office testing of immunologic competence. If, when, and how such testing should be routinely done remain to be decided. A chest x-ray in the newborn nursery prior to discharge does not seem unreasonable. Such a screen would undoubtedly pick up infants with congenital pulmonary or cardiac disease that would otherwise be missed. Routine testing of peak expiratory flow rate is easily introduced into a busy pediatrician's office for children older than four years. A child with peak flow more than two standard deviations below the mean for his height could then be more carefully evaluated. The competence of the humoral antibody system could be tested by a Schick test after routine DPT immunization. These are a few examples of simple diagnostic methods now available for the early detection of treatable pulmonary disease.

We must now consider the possible detection of chronic pulmonary disease outside of Set I, and thus outside of the direct control of the physician. This is clearly the community's area of activity. Increased recognition here must depend on the physician-citizen and on both governmental and private organizations whose mission is the eradication of pulmonary disease. We must include the Division of Chronic Disease Programs, the Division of Regional Medical Programs, the National Institutes of Health, state and city departments of health, the American Academy of Pediatrics, the National Tuberculosis and Respiratory Disease Association, the National Cystic Fibrosis Research Foundation, the American College of Chest Physicians, and others. From one or more of these groups must come the concept, development, and subsequent field trials of the necessary community-wide screening tests.

The problem boils down to a selection of diseases to test for, and this selection in turn depends on a number of factors, such as the nature of the disease, its incidence, its mortality, its morbidity, and its inertia. By the term "inertia" we mean the qualities of acceleration and momentum. Does a disease move rapidly and end quickly (low inertia) or does it start slowly, gain momentum, and end slowly (high inertia)? Diseases of high inertia usually have prolonged periods of true subclinical expression.

Another factor in selecting a disease to screen for would be the expected gains of early recognition. Obviously, both the community and the individual gain from early recognition of tuberculosis. It has been shown that the early recognition of cystic fibrosis is associated with increased longevity, because treatment of a preventive nature can be employed before considerable pulmonary destruction has occurred. Early recognition must have a tangible "pay-off."

The state of the art in screening for a disease must be examined. Is a test available, and, if so, is it cheap, brief, simple, painless, specific, objective, accurate, and precise?

There is no simple approach to the recognition of subclinical pulmonary disease in children. It will depend in part on the development of a bona fide pediatric subspecialty of pulmonary disease. The impetus must come from the pediatrician, regardless of whether he is acting as an individual or within a group.

A reasonable step at this time would be the establishment of a Task Force to study the problem, including defining and listing the various diseases, outlining what is known of their incidence, clinical expression, recognition, and treatment. Such a Task Force, supported by some or all of the interested groups above, could then set priorities for action. Its opinions, published and widely circulated, could serve as documentation for requests to foundations and governmental bodies. After all, the logic of the Venn diagram suggests that the children in the "white" parts of the pulmonary disease sets must first be recognized in order to be treated.

Steven Strong, M.D.

There's little to say about me concerning the September cover photo except that I'm a "struggling" medical resident at the Veterans Hospital. I'll be on Uncle Sam's "war(d)" in a year, and so I'm watching the "Viet(al)" signs . . . (heh heh . . . and Viet Nam suffers from "gram-negative" (red) infiltration . . . mili(t)ary disease . . . and chronic (Tet)perature attacks . . . and all we need is . . . oh you guessed . . . chronic Am(peace)cillin!

The photo was taken during a tour of the National Parks with an old Argus, $300 and a wrinkle-nosed VW.

Keep Hammering

A professor of law said to his students: "When you're fighting a case, if you have the facts on your side, hammer them into the jury, and if you have the law on your side, hammer it into the judge."

"But if you have neither the facts nor the law?" asked one listener.

"Then," answered the professor, "hammer the table."*

Knowledge

If the average person were credited with what he knows and charged with what he thinks he knows but doesn't, he most likely would be rather heavily in debt.

Onions can make even heirs and widows weep.—Benjamin Franklin.

Respiratory Complications of Cystic Fibrosis*

Prevention

WARREN J. WARWICK, M.D.†
Minneapolis, Minnesota

If the pulmonary complications of cystic fibrosis constitute the most severe and malignant pulmonary disease in childhood, causing premature deaths in affected children, and if the pulmonary complications are preventable, we have the basis for a comprehensive preventive medical program.

Six reports of the survival of children with cystic fibrosis not receiving special pulmonary therapies showed first-year mortalities of 33 to 65 percent.[1] The best of these series showed a 50 percent mortality by three and a half years and 90+ percent mortality by 20 years.

Cumulative data from the National Cystic Fibrosis Research Foundation Centers from 1966 to 1967 showed a mortality of 11 percent by age one, and 80 percent by age 20.[2] Cumulative data from the Center at Case-Western Reserve School of Medicine, 1958-1967, showed a 6 percent mortality at age one year and 38 percent at 20 years.[3]

These data clearly indicate that therapy now available can greatly alter the course of cystic fibrosis. But what is the best time to start such therapy?

Shwachman and coworkers reported their experience with infants with cystic fibrosis diagnosed in the first four months of life, eliminating infants with meconium ileus. When their data are compared with the National Cystic Fibrosis Research Foundation Center patients without meconium ileus, we see a decrease in first-year mortality from 8 percent to less than 1 percent for patients with mild or absent lung diseases.

The decreased mortality is also obvious at 10 years of age when the comparative cumulative mortality for the two groups has reached 16 and 8 percent.

Matthews, Doershuk, and coworkers from Case-Western Reserve University had 65 patients in their series who were also diagnosed prior to four months of age. These data include infants with meconium ileus and, because of the small number, no division was made concerning severity of pulmonary complications. When the mortality for this group is compared to the mortality for the whole group of patients treated at that Center, we observe a decrease of first-year mortality from 6 to 4 percent and no deaths after six months of age despite over 200 followup years to ages up to 11 years.[3]

---

*Read at the Regional Continuation Course on Chronic Respiratory Diseases in Children and Adolescents at the University of Minnesota, Minneapolis, September 17, 1968.

†Associate Professor, Department of Pediatrics, University of Minnesota, Minneapolis, Minnesota.

Early Diagnosis

These analyses show that the mortality from the pulmonary complication can be reduced maximally by early diagnosis and intensive treatment beginning at the time of diagnosis. The tools presently in the hands of physicians in practice are a keen sense of suspicion and the sweat test. The physician convinced of the malignant nature of the pulmonary complications of cystic fibrosis and of the benefits of prophylactic pulmonary therapy will order at least two sweat tests on any infant with any of the symptoms in the Table.

TABLE

*Symptoms Suggestive of Cystic Fibrosis.

- Persistent cough
- Recurrent pneumonia
- Atelectasis
- Emphysema
- Asthma
- Hemorrhagic tendency
- Failure to gain
- Steatorrhea
- Jaundice
- Low salt syndrome
- A sibling with cystic fibrosis
- Vitamin A deficiency
- Meconium ileus
- Intestinal obstruction
- Rectal prolapse
- Edema
- Salty skin

However, adequate as such a program of sweat-testing every suspected child could be, the data of Shwachman[4] et al. and of Matthews, Doershuk, and coworkers[3] show that severe, even fatal, pulmonary complications can develop within a few months after birth. Therefore, in order to make the diagnosis before pulmonary complications have begun, physicians will have to develop tests which will be effective in the newborn nursery.

Screening Tests

Three possible newborn nursery screening tests for cystic fibrosis were the leading subjects at a recent National Cystic Fibrosis Research Foundation Center Directors Conference.[5]

One of these, the measurement of the albumin content of meconium has failed to live up to expectations and is now not recommended.

Nail Clippings

The use of neutron activation of the sodium, potassium, and chloride present in nail clippings is being studied at Baylor University, Houston, Texas,[6] and at Children's Orthopedic Hospital and Medical Center, Seattle, Washington.[7] This technique, still in development, excites high hopes because the analytical process can be automated and because, if the test can be made practicable and efficient, sufficient neutron activators exist to analyze nail clippings from every infant born in the United States. However, the state of art is such that false-positive and false-negative results are obtained over 10 percent of the time.

Sweat Test

Sweat-testing with a chloride specific ion electrode has, according to Dr. C. T. Gillespie, reached the stage of feasibility testing. He has proven the technique in a survey of 36,000 children up to age 18 years on Prince Edward Island in 1967. Later in 1967 in a three-month trial of newborn testing in Halifax, Nova Scotia, he found one newborn with cystic fibrosis in the first 300 tested.[5]

Comments

Large-scale feasibility testing of this technique is presently hampered by non-standardized equipment. The current best combination of equipment is the Orion specific ion meter Model 401, the Beckman chloride specific ion electrode Research Model 78527V, the Hydrocollator gel pack heating system, and the Temp block module heater.[8]

When neutron activation analysis of nail clippings or the chloride ion electrode sweat test or another technique makes newborn testing practicable, an estimated 3000 to 4000 new patients will be diagnosed every year. This large number will cause at least two problems. First, application of preventive treatment measures to such a large number of patients is beyond the capability of present cystic fibrosis centers for more than a few years; therefore in most cases care will have to be given by physicians outside of a cystic fibrosis center.

Second, the demands of the present techniques of prophylactic pulmonary therapy are unacceptable to some physicians; hence our present best treatments may not be generally used by all physicians.

However, the large number of newly diagnosed patients may help resolve this problem. Diagnosis of large numbers of newborn infants with cystic fibrosis will permit controlled studies to determine the prophylactic value of the individual items of therapy that are controversial—particularly the use of face masks and tent aerosols, physical therapy, antibiotics, and dietary supplements.

Matching of patients by sex, birth weight, birth complications and family size, and also by random assignment to treatment groups will permit assessment of the value of these and other treatment variables for prevention of the first pulmonary complication. Such studies will eventually prove all aspects of treatment.[5]

Simultaneously with the proving of these items of therapy, there will have to be a broadened post-graduate training program for physicians in practice. This may include special post-graduate courses such as "Chronic Respiratory Diseases in Children and Adolescents," publication of the papers from such a course, formation of clinics satellite to a University Center, special fellowships for short-term study at a University Center, touring lectures, etc.

Conclusions

Prevention of the pulmonary complications of cystic fibrosis will become routine when (1) newborn diagnosis is routine, (2) the test techniques for prevention have been proven by controlled studies, and (3) knowledge of the application of these techniques is common to to all physicians who will have to care for these infants.

Genetic Counseling for Parents[*]

Children with Cystic Fibrosis, Agammaglobulinemia, or Fatal Granulomatous Disease of Childhood

V. ELVING ANDERSON, Ph.D.[†]
Minneapolis, Minnesota

GENETIC COUNSELING involves the use of genetic information in order to promote the welfare of the individual, the family, and society. This becomes important for those types of chronic respiratory disease which have a clearly genetic etiology. When parents know that there is a sizable risk of producing another child with a serious defect, the responsible approach is to consider setting aside the privilege of further reproduction in order to protect the "rights" of children to be well-born.

The significance of such a choice was emphasized by the late Pope Pius XII: "Better warned of the problems posed by genetics and of the gravity of certain hereditary diseases, men of today have, more than in the past, the duty to take account of this increased knowledge so that they might forestall countless physical and moral difficulties for themselves and others. They should be attentive to whatever could cause lasting harm to their descendants and involve them in an interminable succession of miseries."[1]

If a couple is to make free and responsible decisions concerning future pregnancies, they should have: (a) the best information currently available about the genetic risks involved, (b) an interpretation of this information so that they can understand and accept it, and (c) techniques for restricting conception if they so decide. The parents may wish to consider other religious, emotional, or financial factors, but the final decision should be left to them.

The physician who makes the diagnosis of a genetic disease has the primary responsibility for seeing that the parents are informed of the genetic implications. The discussion is best conducted with both parents together, since both share in the need for understanding as a basis for future reproductive decisions.

The estimate of risk for the next pregnancy requires an accurate diagnosis and adequate information about the family history. A statement of "negative family history" is seldom sufficient. As a minimum, the record should answer the following questions: (1) Was the patient twin-born? (2) What was the outcome of each of the mother's other pregnancies? Were any children affected with a similar disease? (3) Are the mother and father related by blood? (4) How many brothers and sisters have the parents had? Has any had a problem similar to that of the patient?

Mode of Inheritance

A decision as to the mode of inheritance is usually not difficult. All cases of cystic fibrosis follow an autosomal recessive inheritance, and all cases of fatal granulomatous disease of childhood appear to follow an X-linked recessive pattern. On the other hand, some cases of agammaglobulinemia are autosomal recessive, but others are of an X-linked recessive type. Parental consanguinity would strongly suggest an autosomal type, while the presence of affected maternal uncles would make X-linkage likely. If the laboratory data are equivocal, or if the family history appears to contradict the provisional diagnosis, further consultation would be advisable.

Two notes of caution may be helpful. With the relatively small current family size, isolated cases of genetic disease (having no family history of the condition) can be expected fairly often. The presence of disease in a girl does not always exclude X-linkage, since the occasional expression of an X-linked trait in carrier females has been observed.

Risks for the Next Pregnancy

In autosomal recessive traits (cystic fibrosis and some cases of agammaglobulinemia) the risk for the next pregnancy is 25 percent. The explanation of this risk to the parents may take some time, however.[2] They will need to understand that both husband and wife carry a "hidden" gene, and that the affected child by chance received a "double dose." There is no reason to blame themselves or each other for what has already happened, but they are now in a position to make a conscious choice about another pregnancy. The discussion may take into account their own adequacy in being able to care for another such child, as well as the severe health restriction that the child would face.

If contraception is attempted but fails, the 25-percent risk of severe defect in the child could be considered a fetal indication for abortion. Rather than run any risk at all, the couple may prefer voluntary sterilization for husband or wife.

In X-linked recessive situations (fatal granulomatous disease and some cases of agammaglobulinemia) the risk for the next pregnancy is 25 percent *or less*. The possibility of a lower risk arises from the fact that one third of the *isolated* cases of an X-linked *lethal* trait will result from a newly mutant gene on the X-chromosome from a non-carrier mother. In these newly mutant cases the risk for the next pregnancy is essentially zero. For example, if the mother of an affected boy has two normal brothers and two normal sons and no other affected relatives, there is only a 24-percent chance that she is a carrier and thus a 6-percent chance that the next child will be affected (Table 1). If there had been one additional affected brother or son, we would know that she *is* a carrier and that the risk for the next pregnancy would be 25 percent. If a woman is demonstrated to be a carrier, neither sterilization of her husband nor donor insemination

TABLE 1

Probability That the Mother of an Isolated Case is a Carrier for an X-Linked Lethal Recessive Trait

Number of unaffected brothers (with none affected)	Number of unaffected sons (with only one affected)				
	None	One	Two	Three	Four
None	0.67	0.50	0.33	0.20	0.11
One	0.60	0.43	0.27	0.16	0.09
Two	0.56	0.38	0.24	0.14	0.07
Three	0.53	0.36	0.22	0.12	0.07

Adapted from Murphy[3]

TABLE 2

Probability That a Woman is a Carrier for an X-Linked Recessive Trait

Steps from known carrier	Number of unaffected sons (with none affected)				
	No sons	One	Two	Three	Four
One	0.50	0.33	0.20	0.11	0.06
Two	0.25	0.14	0.08	0.04	0.02
Three	0.13	0.07	0.03	0.02	0.01
Four	0.06	0.03	0.02	0.01	0.004

Adapted from Murphy[3]

would be indicated.

Other Relatives

The risk to other relatives should also be considered. In the case of cystic fibrosis, each sibling of a parent (of affected children) has a 50-percent chance of being a carrier, and their spouses have about a 4-percent chance. The over-all risk for a cousin of an affected child is about 1/200.

If a cystic fibrosis patient marries, all children will be carriers of a gene for the trait. In such a marriage the spouse should always be tested for carrier status to reduce the chances of producing an affected child. This problem is less critical for males with cystic fibrosis, since most are sterile.[4]

The need to check other relatives is greater for X-linked recessive traits. If a sister of a known carrier (or of an affected male) has two normal sons (and none affected), there is a 20-percent chance that she is a carrier and thus a 5-percent chance that her next child will be affected (Table 2). If she has one or more affected sons, she is known to be a carrier.

Concluding Comments

Tests for carrier detection are not yet accurate and simple enough for premarital counseling in the general population. Even for a condition as common as cystic fibrosis, at least 800 persons would have to be tested in order to detect one couple in which both are carriers. However, carrier tests are most helpful for close relatives of affected persons.

The services of a geneticist as consultant may be helpful in interpreting a family history, in tracing family members, or in other ways. Within Minnesota such consultation can be obtained from the Human Genetics Unit of the Minnesota Department of Health. A directory of genetic services in other states has been published recently.[5]

From an 18th Century French Drug Dictionary

"All parts of man, his excrescences and excrements, contain oil and sal volatile, combined with phlegm and earth. Skull, brain, and calculus are employed in medicine, and are referred to in their proper places. Burning hair, smelt by patients, will counteract the vapors. Moss of the human skull, human blood, and human urine all have their uses in medicine. The saliva of a robust young man, taken fasting, is an antidote against the bites of serpents and mad dogs. Wax from the ears is good against whitlows. Nails from the fingers and toes, given internally either in substance or infused in wine, make a good emetic. Women's milk is pectoral, good in phthisis, and useful to apply to inflamed eyes. Fresh urine, two or three glasses drunk in the morning fasting, is good against gout, hysterical vapors, and obstructions. It may also be applied externally in gout and in skin complaints. Excrement of man can be applied to anthrax, plague bubos, and quinsies. Dried and powdered, it is recommended in epilepsy and intermittent fevers. Dose, one scruple to a drachm."*

What's New

AMDOC and FSTPP

In late 1967, the committee on preceptorships of the Pennsylvania Academy of General Practice, organized to provide medical students with family practice exposure, extended this concept to foreign service programs. FSTPP condenses the title of the Foreign Service Team Preceptor Program which combines the teaching talent of the physician with the searching attitude of the student into a team approach for service on foreign soil. Specifically one or two doctors are matched with from one to three medical students and assigned to an overseas station.

AMDOC short for AMerican DOCtor is a non-profit, non-sectarian, non-governmental related corporation dedicated to the ultimate placement of physicians and students into suitable needy foreign locations.

Junior and senior medical students are eligible to apply for FSTPP and may do this through formal application to AMDOC or by writing to the Pennsylvania Academy of General Practice. Physician preceptors may apply in the same fashion. Period of service varies depending upon team members and location, but a minimum of one month is suggested.

Mead-Johnson Laboratories

Mucomyst, acetylcysteine, is now available in a 10% solution, one-half the strength of the original product. *Mead Johnson Laboratories* announced the introduction of this new strength, emphasizing its applicability in the patient who uses Mucomyst at home in his nebulizing unit.

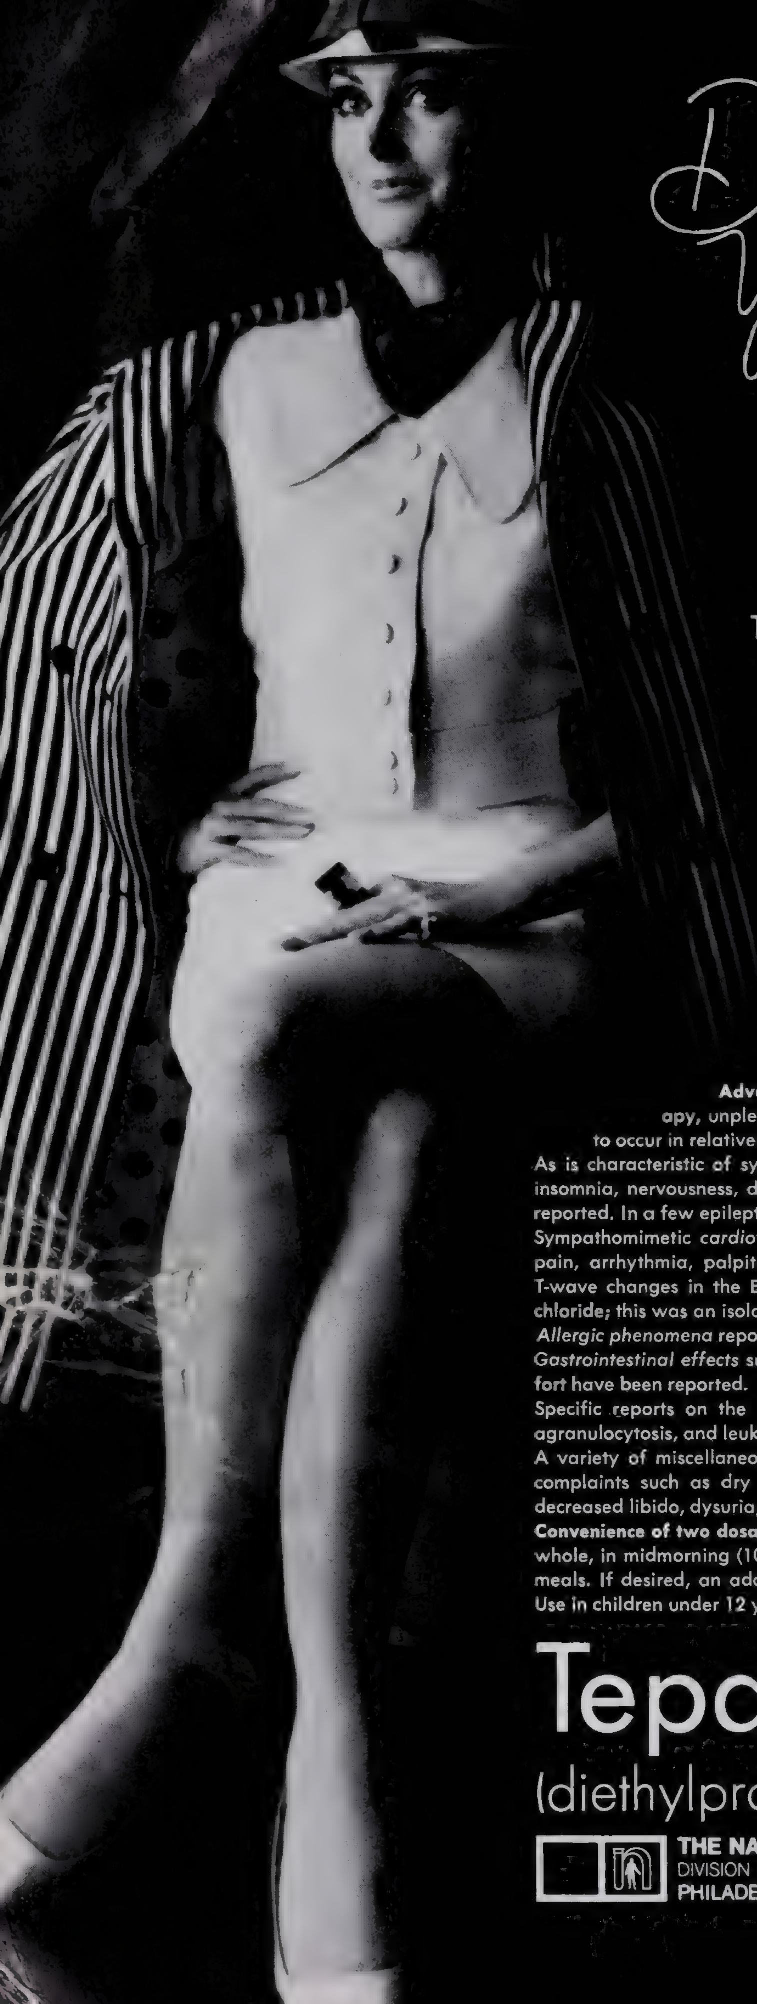
mn on Madeline Island"

Robert W. Schulz, M.D.

OCTOBER, 1969



TEPANIL—the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence.

As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported.

Sympathomimetic *cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others.

Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema.

Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported.

Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia.

A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride)

DECLOSTATIN® 300 b.i.d.

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropr
measures should be taken.

In infants, increased intracranial pressure with bulging fontanels
been observed. All signs and symptoms have disappeared rapidly u
cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, d
rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculo
ular and erythematous rashes; a rare case of exfoliative dermatitis
been reported. Photosensitivity; onycholysis and discoloration of
nails (rare). Kidney—rise in BUN, apparently dose related. Trans
increase in urinary output, sometimes accompanied by thirst (ra
Hypersensitivity reactions—urticaria, angioneurotic edema, anaphyla
Teeth—dental staining (yellow-brown) in children of mothers given
drug during the latter half of pregnancy, and in children given the c
during the neonatal period, infancy and early childhood. Enamel h
plasia has been seen in a few children. If adverse reaction or idio
crasy occurs, discontinue medication and institute appropriate ther

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Shoul
given 1 hour before or 2 hours after meals, since absorption is impa
by the concomitant administration of high calcium content drugs, f
and some dairy products. Treatment of streptococcal infections sh
continue for 10 days, even though symptoms have subsided.

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization—provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste—confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[1]

Concomitant relief of G. I. gas distress—provided by the proven antiflatulent action of simethicone.[2]

Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonfuls to be taken between meals and at bedtime, or as directed by physician.

One of the best things you can do
for the cold sufferer

Ornade® Spansule® brand of sustained release capsules

Trademark
Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

Prompt relief from nasal congestion and hypersecretion due to colds.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction.
Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.
Usage In Pregnancy: Use in pregnancy, nursing mothers and women who might bear children only when potential benefits have been weighed against possible hazards.
Note: The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.
Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible adverse reactions of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, incoordination, tremor, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported.
Supplied: Bottles of 50 capsules.

One capsule q12h for round-the-clock relief

Dermatology in Minnesota

THE ECONOMIC loss from cutaneous medical problems recently was estimated conservatively as representing 1.43 billion dollars per year.[1] This figure includes the cost of medication, hospitalization, losses in wages, and funds for compensation. No estimate of Minnesota's share of this loss is available, but our climate, the size of our population and the nature of the industry of the state indicate that probably our share is lower than that of many other states.

We are well provided with specialists in dermatology. There are 68 dermatologists in Minnesota, or one per 52,000 of the general population. Minnesota ranks thirteenth in the number of dermatologists within its borders. Missouri, with one million more population, has only three more dermatologists. The ranking of Minnesota in terms of dermatologists-to-population is even better, for it is seventh, ahead of New Jersey, Michigan, Ohio, Pennsylvania, Texas, Illinois and Wisconsin. This indicates that we not only train dermatologists in our state, but also retain them and attract others to practice here.

Nationally, dermatology ranks after internal medicine and pediatrics in terms of numbers of persons in full-time medical specialty practice. In 1966 there were 3,674, of whom 2,111 were board-certified. By comparison, one must note that at the same time only 884 of 2,047 cardiovascular specialists were board-certified and only 8,551 of 16,417 pediatricians were board-certified.

Minnesota has been regarded as a center of excellence in training in dermatology. Beginning with the internationally recognized program developed under Dr. Henry E. Michelson at the University of Minnesota and continuing with the sophisticated basic sciences and clinical sciences approach under the direction of Dr. Francis Lynch, the Department of Dermatology at the University of Minnesota has maintained its position as a leader among such facilities in the Big Ten universities. Minnesota and Michigan are acknowledged to be the prime schools of dermatology training. The Section of Dermatology at the Mayo Clinic has a postgraduate training program which was brought to national prominence by Dr. Paul A. O'Leary and has continued to advance under the guidance of Dr. Louis A. Brunsting and Dr. Robert R. Kierland. Minnesota trains between 5 and 7% of the nation's dermatologists, or, stated differently, has 32 men in training at any one time. Between 1963 and 1968 the number of training programs in dermatology declined by 30%; but at the same time, the number of approved residencies increased to 530.

Thirty-two training programs in dermatology, made possible by grants from the National Institutes of Health, are currently in operation. These programs have been developed to train dermatologists to meet the requirements for a full-time career in the basic and clinical sciences related to dermatology. Two of the centers made possible by these grants are in Minnesota, at the University of Minnesota and at the Mayo Clinic. Both institutions have trained a large number of the heads of departments of dermatology in medical schools in this country,

Treatment of Coronary Disease*

Pathologic Limitations

JESSE E. EDWARDS, M.D.
St. Paul, Minnesota

WHEN MAN MAY COME closer to the moon than the distance between St. Paul and Rochester, when one man may live with the heart of another, the word limitation must allow for changing parameters.

In recent years progress in medicine has been so great that, in discussing anatomic limitations to therapy in coronary disease, one must recognize certain conditions. Thus, limitation with regard to medical treatment without the facilities of an acute cardiac care unit differs from that with such a unit. Under certain circumstances limitation may be nearly absolute from the viewpoint of medical treatment, while surgical treatment may offer predictable beneficial results. In any case, that which is limited today may be commonplace tomorrow. It is apparent that our discussion today of pathologic limitations to the treatment of coronary arterial disease must reflect that what is pertinent today is subject to change within the future, in some instances within the near or very near future.

Coronary Atherosclerosis

The clinical opinion that coronary atherosclerosis is present, either from a history of angina pectoris, from myocardial infarct having occurred, or from both, is commonplace, and much thought has been given to means of altering this fundamental arterial lesion. One aim has been through application, in reverse, of those two factors which have been identified as having an atherogenetic tendency: elevated serum lipids and hypertension. The high content of collagen and extracellular lipids in the intimal lesion appears to fix the lesion securely—so securely, in fact, as to be resistant to significant alteration by any manipulation of diet and blood pressure (Figure 1a).

In addition, an occasional arterial segment is the site of a thrombus in the organized stage (Figure 1b). This process is characterized by

---

*Presented before the joint meeting of the Minnesota Heart Association and the American Therapeutic Society, Minneapolis, January 19, 1969.

This study was supported by Public Health Service Research Grant 5 RO1 HE05694 and Research Training Grant 2 T1 HE05570 from the National Heart Institute.

the presence in the lumen of connective tissue with varying degrees of vascularization. The connective tissue here, as in the fundamental atheroma, is essentially scar tissue, a substance highly resistant to change.

It is evident that if dietary and other manipulations are to affect atherosclerosis, these must be applied before the lesion develops. In practical terms this means that measures aimed at preventing atherosclerosis must start at and be continued from early ages, from adolescence or even from childhood.

Recognizing that the established lesion is not readily changed by manipulation of atherogenic factors, attention has been directed toward surgical alteration of lesions, alterations which might include removal of atheromas or removal of segments (with grafting) of diseased coronary arteries. Swedlund and associates[1] attempted to determine how practical was the potential for such surgical procedures. They studied specimens of hearts from patients who had had clinical evidence of coronary disease and observed that in only a limited percentage of the cases (18 percent) was the lesion localized to one focus, while in the remainder, multiple lesions were encountered. This is a relatively small percentage of patients who might receive considerable benefit from surgical treatment of the fundamental lesion.

Acute Myocardial Infarction

A number of problems relate to acute myocardial infarction which represent relative or absolute limitations to treatment by today's standards:

Shock

Shock occurring with acute myocardial infarction may be a manifestation of loss of muscle, either from the acute event alone (Figure 2a) or added to loss from earlier episodes of infarction (Figure 2b) to the degree that there is an absolute and irreparable loss of efficiency of the pumping function of the left ventricle. It is important to emphasize, however, that shock may be a manifestation of factors other than myocardial and that, when these are overcome, it becomes evident that the left ventricle has sufficient reserve to perform in an efficient manner.

Cardiac Rupture

Rupture of the heart (including rupture of the free wall of the left ventricle, of the ventricular septum, or of a papillary muscle) is not uncommon among cases of fatal acute myocardial infarction, occurring in about 15 percent of such cases. If one were to accept that 15 percent of patients with acute myocardial infarction fail to survive, one might estimate that among one hundred instances of acute

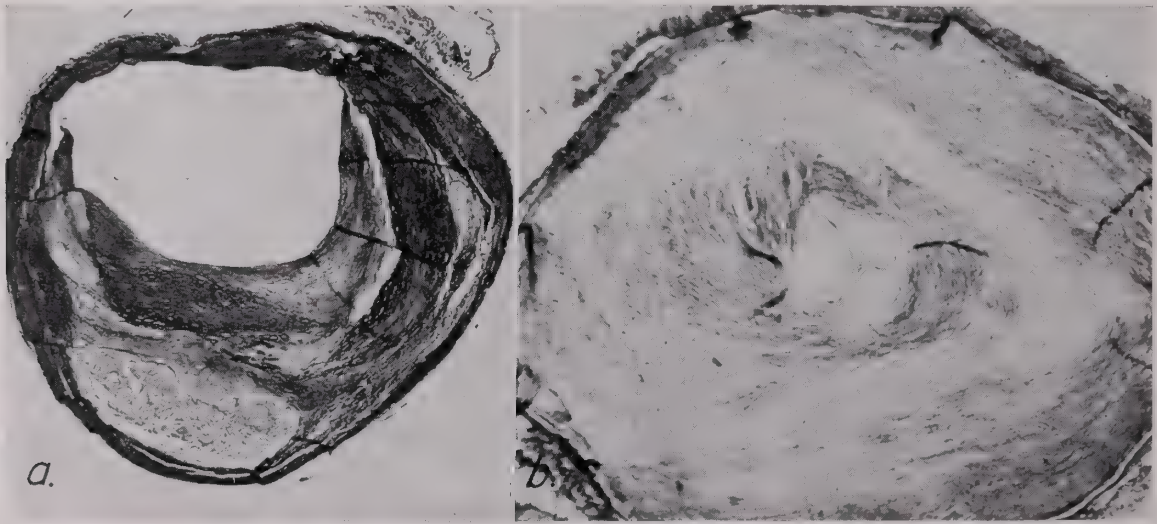

Fig. 1—Photomicrographs of atherosclerotic coronary arteries. *a.* The basic atheroma is composed of collagen and extracellular connective tissue. Elastic tissue stain; x 15.

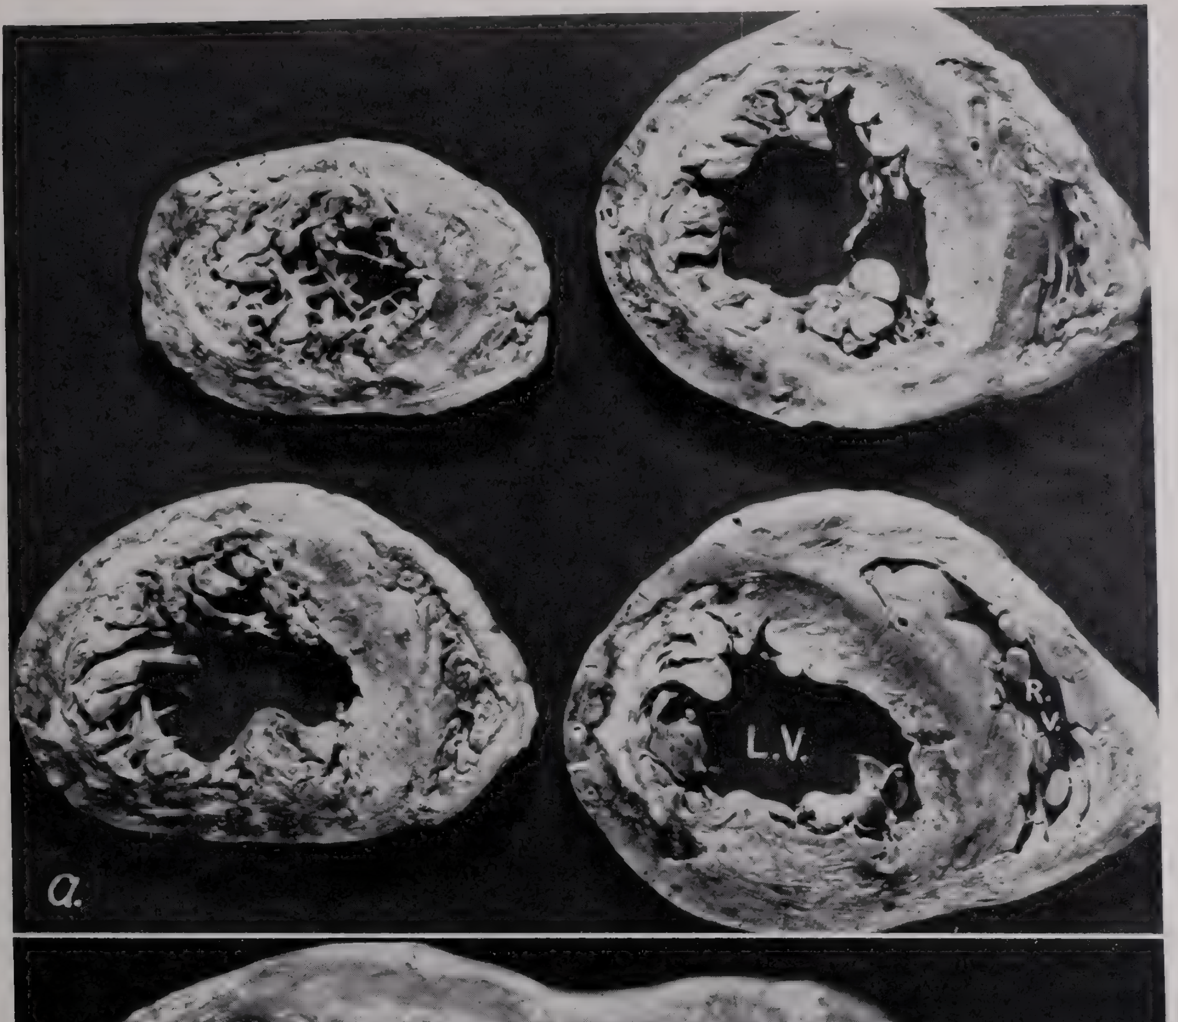

Fig. 2—Extensive myocardial infarction. *a*. The anterior, lateral and posterior walls of the left ventricle are involved by extensive acute infarction. *b*. In addition to a healed subendocardial anterior infarct, the posterior wall shows extensive acute transmural myocardial infarction. In these illustrations, as well as in others, L. V. = left ventricle; R. V. = right ventricle.

myocardial infarction, there occur about two cases of rupture of the heart. In most instances, this complication represents a major barrier to effective therapy of the patient since death usually (but not always) follows shortly after the episode of rupture. (See below for consideration of left ventricular aneurysm developing from rupture of the heart.)

All instances of rupture of the heart occur in transmural myocardial infarction and most commonly about three to four days after the onset of the acute infarction.

About 85 percent of the cases of rupture involve the free wall of the left ventricle. The complication begins as a laceration of the left ventricular wall at the junction of infarcted and non-infarcted muscle. Blood from the cavity extends from the laceration through the left ventricular wall and into the pericardial sac (Figures 3 and 4). Classically, acute cardiac tamponade and death from the resulting hemopericardium occur within minutes after the extravasation of blood into the pericardial cavity.

Rupture of the ventricular septum, more commonly a complication of posterior than of anterior myocardial infarction, occurs in about ten percent of all cases of cardiac rupture (Figure 5). The resulting acquired ventricular septal defect varies in its manifestations. In those instances where the opening is wide, the circulation rapidly fails. Less commonly, the circumstances are such as to allow the patient to live for varying periods of time, even years after the event of rupture. Such patients are candidates for surgical closure of the acquired defect.

The least common type of rupture of the heart is characterized by loss in continuity of a papillary muscle (Figure 6). This complication, which represents about five percent of all instances of rupture of the heart, usually involves the posteromedial papillary muscle in

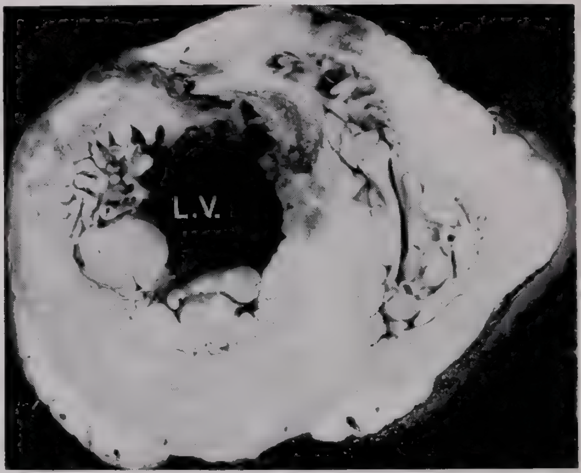

Fig. 3—Transmural myocardial infarction of anteroseptal region of left ventricle with laceration of left ventricular wall characteristic of rupture of the heart.

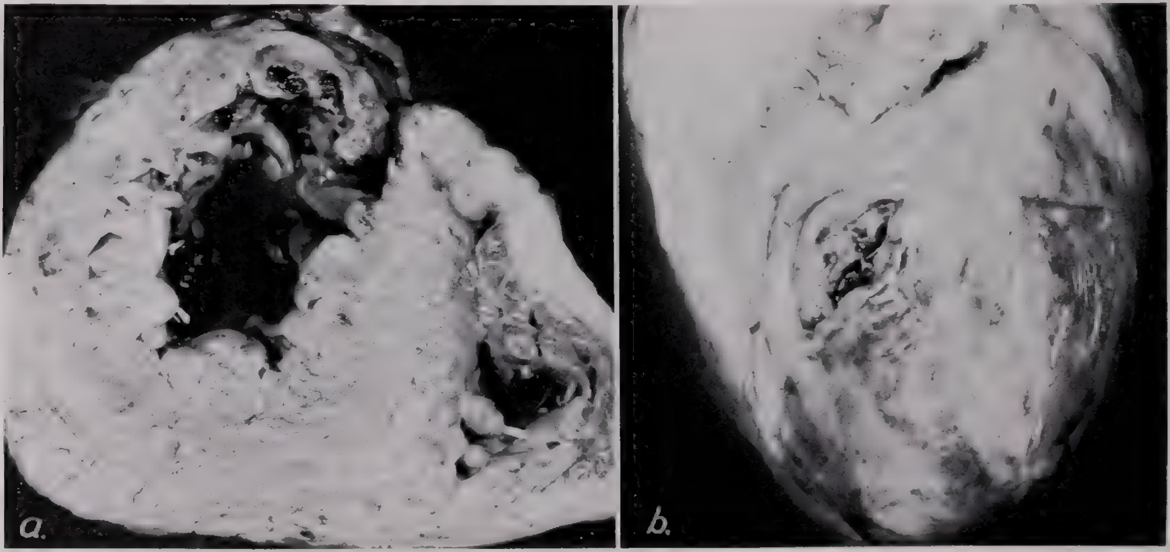

Fig. 4—Rupture of the anterior wall of the left ventricle characterized by an opening larger than average. *a.* Cross section of the ventricular portion of the heart. The rupture site lies at the periphery of the myocardial infarct which is at the junction of the anterior wall and ventricular septum. *b.* External view of the anterior wall of the heart showing a gaping wound which led to hemopericardium. In most instances, the epicardial aspect of the rupture is less distorted than in this instance.

continuity with infarction of the posterior left ventricular wall. The resulting mitral insufficiency is usually of major proportion and responsible for early significant failure of the circulation and death.

While the onset of major mitral insufficiency in patients with acute myocardial infarction is often the result of rupture of the papillary muscle, there are exceptions (Figure 7). Extensive infarction of a papillary muscle without rupture may, on occasion, be responsible for significant incompetence of the mitral valve. Before leaving the subject of rupture of the heart, reference should be made to *hemopericardium complicating acute myocardial infarction in the absence of cardiac rupture.* Such relatively uncommon situations represent bleeding into the pericardium from an organizing pericarditis. Fibrinous pericarditis in myocardial infarction is, for practical purposes, a complication of transmural infarction.[2] When present, the pericarditis is always found over the infarct; but in some cases it may involve the pericardium diffusely. In such cases, in particular, significant hemorrhage may occur during that stage of the pericarditis when a layer of granulation tissue has developed as part of the process of organization of the inflammatory process. While a program of anticoagulation has a positive influence in causing bleeding from pericarditis, hemorrhage of significant proportion may occur even when no anticoagulants have been administered.

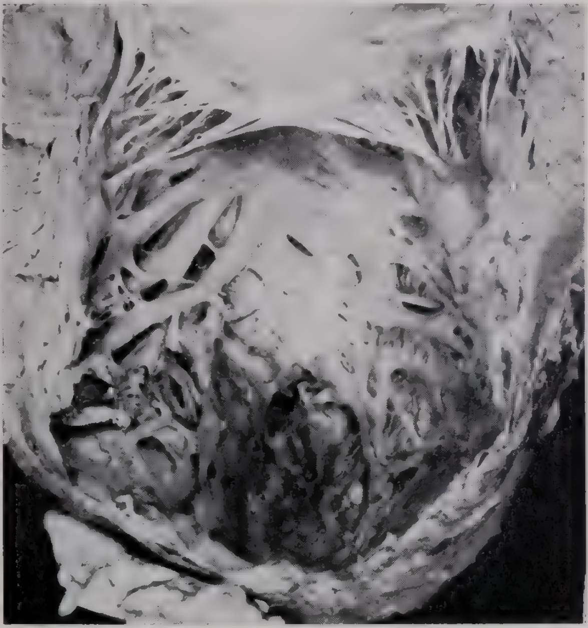

Fig. 5—Rupture of ventricular septum. Interior of left ventricle. The point of the arrow lies at the site of a rupture of the ventricular septum. In this instance there is extensive infarction, the rupture occurring at the junction between the infarcted and non-infarcted portions of the septal wall.

Fig. 6—Rupture of the posteromedial papillary muscle of the left ventricle. The ragged edges (between arrows) of the ruptured papillary muscle are evident. The upper remnant of the papillary muscle along with the chordae is looped through an interchordal space.

Fig. 7—Extensive infarction of the left ventricular wall represented by the lighter zone in the muscle and associated with infarction of the postero-medial papillary muscle (P.-M.). The latter, discolored in the fresh specimen, shows atrophy in this photograph.

Cardiac Irregularity

Arrhythmias, although occurring commonly during episodes of acute myocardial infarction, usually leave no specific signs that can be recognized anatomically. Only uncommonly does the pathologist find infarction of the major conduction tissue (as part of a posterior-basal myocardial infarct) from which he might infer that atrioventricular dissociation has occurred. From clinical experience ventricular fibrillation is recognized as a common basis for the sudden death that may occur in patients convalescing from acute myocardial infarction. In such cases pathologic study supplies evidence in a negative way that is consistent with such a serious arrhythmia.

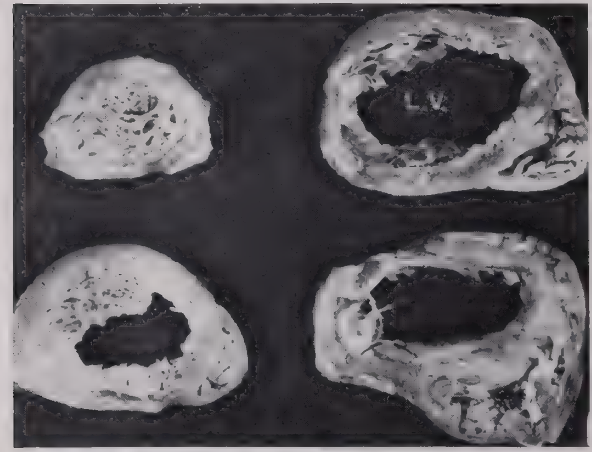

Fig. 8—Cross sections of the ventricular portions of the heart in a case with extensive healed myocardial infarction leading to congestive cardiac failure.

The negative evidence takes the following form. The clinically recognized infarct is found but no additional lesions are identified which would explain the sudden catastrophe. Search at the periphery of acute myocardial infarcts shows viable muscle intermingled with infarcted muscle. As infarction is present in the general area, one concludes that ischemia had been present and that it had been shared by the muscle which survived. Such accumulations of living muscle are probably potentially dangerous foci for spontaneous generation of uncoordinated impulses.

Thromboembolism

Thromboembolism continues to represent an element to recovery in acute myocardial infarction; nevertheless, pulmonary embolism appears to be less common today than two

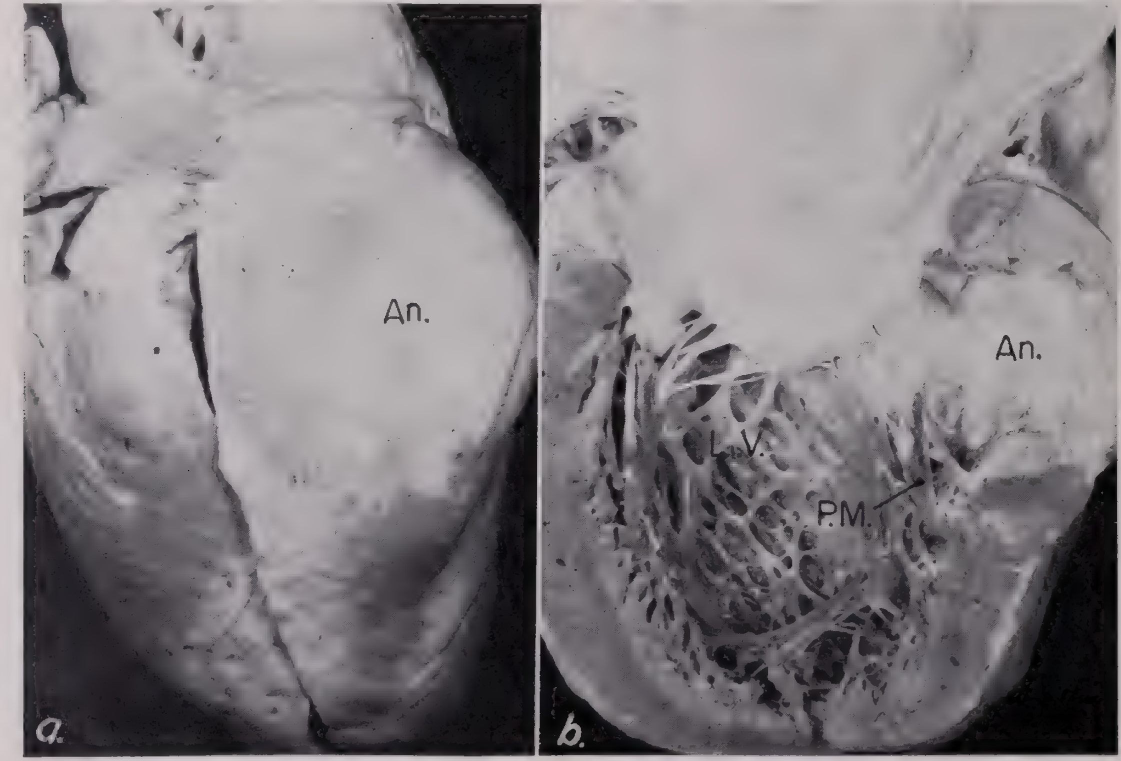

Fig. 9—Aneurysm (An.) of posterior wall of left ventricle. *a.* External view of heart viewed from left. *b.* Section through the aneurysm and adjacent portion of the left ventricle. In this position, the aneurysm lies closely aligned with the posteromedial papillary muscle (P.M.).

decades ago. This may reflect the fact that in the treatment of acute myocardial infarction administration of anticoagulants and early ambulation are common practices.

In some cases with infarction of extracardiac organs, the evidence strongly favors embolism from a complicating left ventricular thrombus. In other cases, the evidence for embolism is not clear, infarction of an extracardiac organ possibly resulting from a combination of lowered blood pressure and arterial disease located in the organ infarcted. In general, the following rule holds true, namely, that systemic arterial thromboembolic complications usually attend large (transmural) infarcts when there is myocardial failure rather than with those of subendocardial distribution.

Healed Myocardial Infarction

The state of patients carrying healed myocardial infarcts is so broad as to vary from no evidence of disease to irreparable cardiac failure.

For those patients with evident disability, the clinical state takes three main patterns:

Cardiac Failure from Muscle Loss

Congestive cardiac failure from extensive loss of muscle, other than that associated with a left ventricular aneurysm, is usually the result of several episodes of myocardial infarction, although the factor of multiplicity of lesions may not have been apparent clinically (Figure 8). In some patients each of the several areas of infarction is healed, the problem being one of chronic inadequacy of the myocardium. In other patients, the state of cardiac efficiency may have been maintained until an additional acute myocardial infarct makes its appearance. With this event, irreversible failure of the pumping function of the heart may become established as a consequence of the additional loss of muscle incident to the new infarct.

Aneurysm

Left ventricular aneurysm is usually the result of myocardial infarction; in such circumstances the underlying lesion is of the transmural type.

Classically, some myocardial tissue remains in the zone of the infarct, and the thinned wall gradually bulges to form a true aneurysm (Figures 9 to 11). Less commonly, left ventricular aneurysms complicating myocardial infarction are of the false type (Figure 12), which result from rupture of the free wall, but without resulting hemopericardium. In such cases, adherent pericardium tends to restrain the extent of the hematoma; the latter, in turn, organizes to form a fibrous wall of a cavity that communicates (usually through a narrow opening) with the left ventricular cavity. In general, the behavior of left ventricular aneurysms is the same, whether of the true or false type.[3]

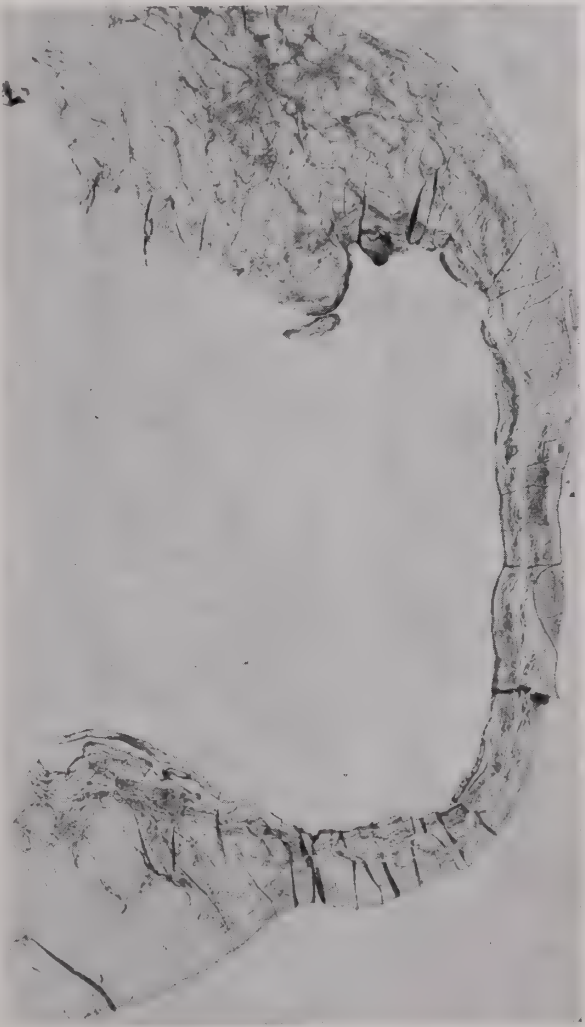

Fig. 10—Low power photomicrograph of left ventricular aneurysm shown in Figure 9. This aneurysm is of the true variety; remnants of myocardium appear in the aneurysm wall. Elastic tissue stain; x 6.

Some patients with left ventricular aneurysm may exhibit no apparent disability; but, in general, the patient with a left ventricular aneurysm tends to exhibit some loss of left ventricular efficiency, at times to the point of overt congestive cardiac failure. The basic problem is that, during ventricular systole, the wall of the aneurysm bulges outward, while the rest of the muscle contracts. The waste of energy involved in the paradoxical motion of the aneurysm may be the important factor underlying left ventricular failure. Additional factors are involvement of a papillary muscle by the underlying infarct (with a tendency toward mitral insufficiency) and the general factor of loss of a large area of infarction which underlay the formation of the aneurysm.

At present, when resection of a left ventricular aneurysm is possible, certain limitations should be emphasized. In the majority of cases, the underlying infarct is anterior in position, with some, but usually limited, involvement of the anterior papillary muscle.

Less commonly, the underlying infarct lies in a posterior position and may concomitantly involve the posteromedial papillary muscle extensively. From the point of view of damaging a papillary muscle by resection of a left ventricular aneurysm, those aneurysms lying anteriorly seem to be less vulnerable than those lying posteriorly.

Regarding indications for resection, the major one is congestive failure, a lesser one is recurrent systemic embolism from the thrombus that almost invariably lies in the cavity of the aneurysm.

Rupture of a ventricular aneurysm is an uncommon event and at present is less likely to occur than are serious complications of aneurysmal resection.

When a surgical procedure in any part of the heart leaves a blind recess of a cavity, a thrombus is apt to form. This has been demonstrated repeatedly in cases of "closed" mitral commissurotomy when the left atrial appendage is incompletely resected. Similarly, a recess left after resection of a left ventricular aneurysm invites the formation of a mural thrombus and the chances of complicating systemic embolism (Figure 13).

Mitral Insufficiency

Mitral insufficiency occurring as part of a healed myocardial infarction probably has a complex basis in most cases.

In those patients with extensive loss of muscle and congestive cardiac failure, several factors appear to contribute to this valvular dysfunction. Among these is dilatation of the left ventricular chamber with (a) secondary enlargement of the mitral orifice and (b) altered orientation of the papillary muscles. Frequently the papillary muscles are sites of infarction along with the free wall (Figure 14). Involvement of these structures is probably a contributing factor in mitral insufficiency.

In some situations (and not uncommonly) one finds a healed posterior subendocardial scar of myocardial infarction along with a scarred posteromedial papillary muscle. In such cases the left atrium is often found enlarged, but a positive correlation with clinical evidence of mitral insufficiency does not consistently occur.

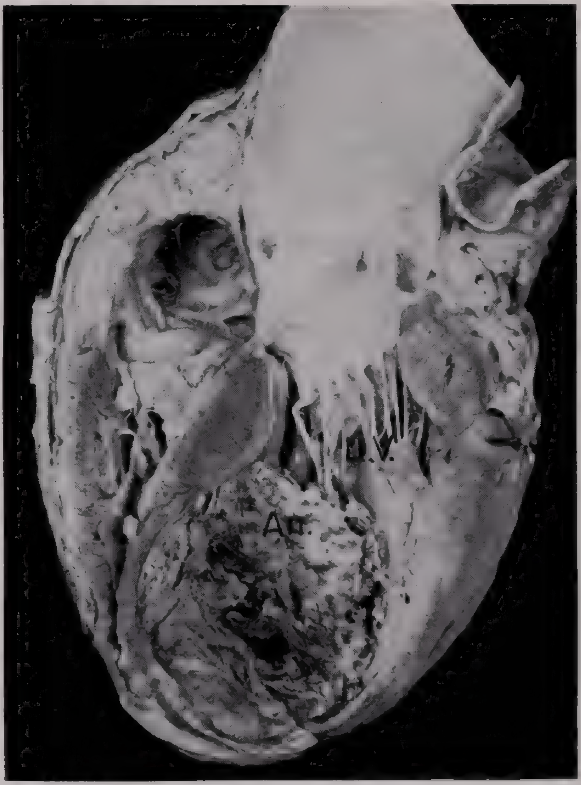

Fig. 11—Aneurysm of left ventricle resulting from infarction of anteroseptal region of left ventricle. Characteristically, the aneurysm contains a mural thrombus.

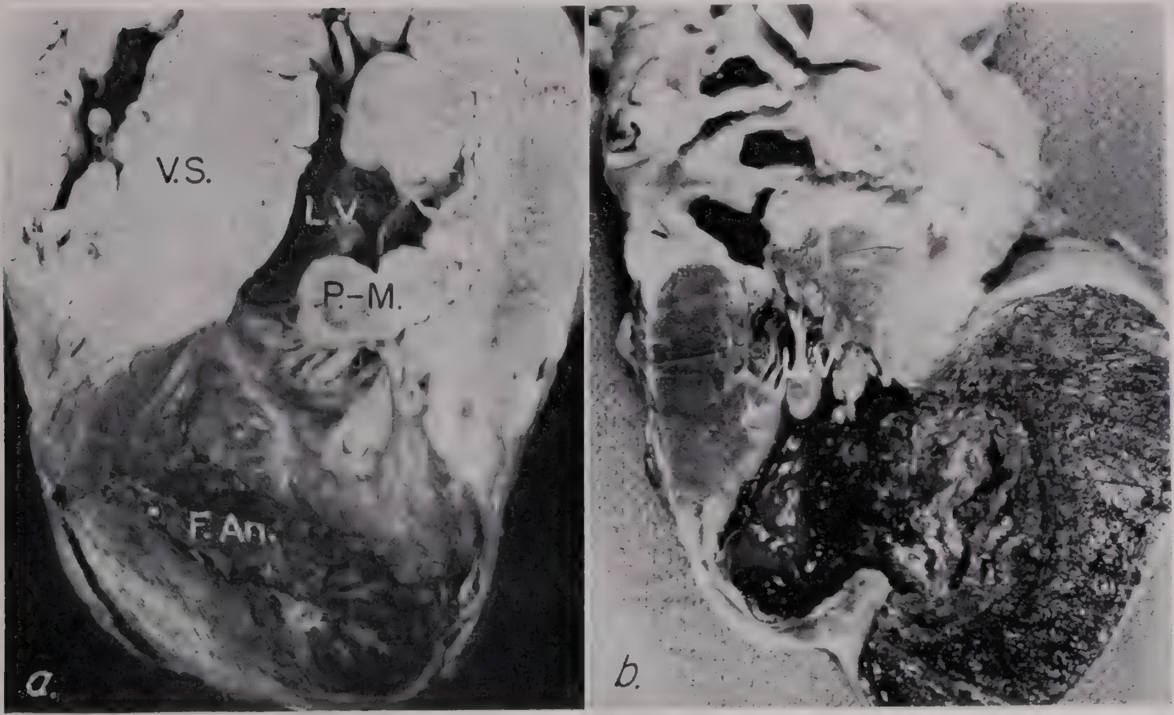

Fig. 12—Two examples of false aneurysm (F. An.) of the left ventricle resulting from rupture of heart. *a.* The heart is sectioned in a tangential way, showing the false aneurysm at the junction of the ventricular septum (V. S.) and the posterior wall of the left ventricle. P.-M. = posteromedial papillary muscle. *b.* Sagittal section through the left ventricle showing a characteristic false aneurysm in which the neck of the aneurysm is considerably more narrow than the fundus.

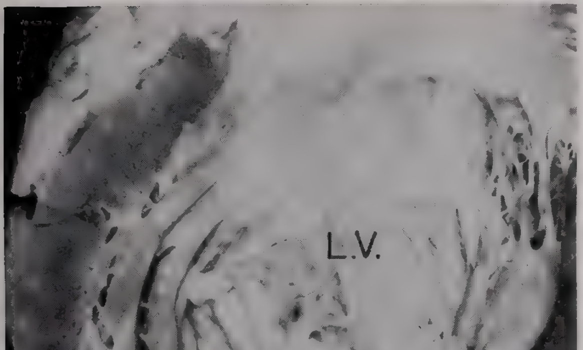

Fig. 13—Interior of left ventricle showing site of previous resection of a left ventricular aneurysm. At the recess, resulting from the excision and suture at the site of resection of the aneurysm, there is a thrombus (between arrows) which represents a potential source for embolism.

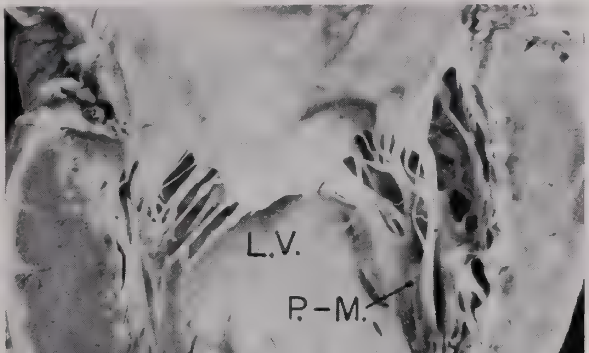

Fig. 14—Interior of left atrium and ventricle in an instance of subendocardial posterior myocardial infarction with concomitant involvement of the posteromedial papillary muscle (P.-M.). The latter is markedly atrophic. Such a lesion may underlie mitral insufficiency.

Conditions Associated with Coronary Disease

A distinct limitation to the treatment of coronary disease is that other diseases may be associated.

Hypertension and Calcific Aortic Stenosis

In the presence of hypertension or calcific aortic stenosis, associated with acute myocardial infarction, the tendency for development of congestive cardiac failure is greater when myocardial infarction occurs than in those instances wherein myocardial infarction is not associated with a condition causing myocardial strain.

Diabetes

Diabetes not only exerts an effect favorable to atherosclerosis and myocardial infarction but, in the event of acute myocardial infarction, may tend to upset the balance of diabetic control.

Myxedema

A trying factor is myxedema. This condition favors the development of atherosclerosis. The increased metabolic rate resulting from treatment of myxedema tends to favor the development of myocardial ischemia.

Cerebral Vascular Disease

Cerebral vascular disease with ischemic loss of cerebral tissue may represent a serious complication of myocardial infarction. In other instances, this condition is coincidentally present as a factor which tends to complicate the management of the total case.

Among patients with aortic atherosclerosis of degrees sufficient to cause either an aortic aneurysm or thrombotic occlusion of the abdominal aorta, coronary atherosclerosis is commonly present, a factor which represents a potential for serious acute complications among those patients who manifest protracted hypotension incident to bleeding from the aneurysm. Also, underlying coronary disease and its complications represent the basis for restricted longevity in those patients who survive appropriate surgical procedures upon the aorta.

Duodenal Ulcer

While one could continue into many other ramifications regarding coronary and associated diseases, I have chosen to conclude with the common problem of duodenal ulcer.

For clinicians I need not enlarge on the problem of myocardial infarction complicating the state of bleeding duodenal ulcer. Equally obvious is the problem of precipitation of duodenal hemorrhage by anticoagulant therapy for myocardial infarction.

The pathologic limitations to the treatment of coronary disease become less absolute with time. Yet a constant limitation among patients with varying manifestations of coronary disease is the ever present underlying lesion, the coronary atheroma, a lesion which, like the sword of Damocles, while not necessarily dropping, threatens to inflict its damage yet again.

Summary

Anatomic limitations in the treatment of coronary disease are relative to the state of development of medicine and to the facilities available for care of the patient.

Direct attack upon the underlying atheroma is limited from a dietary point of view and relatively limited from a surgical point of view by virtue of the usually extensive distribution of lesions.

In acute myocardial infarction, limitation depends upon the extent of loss of muscle and upon specific complications such as rupture of the heart.

In patients with healed myocardial infarction, therapy is limited by the extent of loss of muscle, either from the distribution of the healed infarcts or from the addition of a new acute infarct.

Many patients with coronary disease suffer from additional conditions which either alone or together with the coronary disease represent major barriers to success in therapy. Such conditions include hypertension, valvular disease, diabetes and myxedema.

Suicide and Related Clinical Problems

CARL P. MALMQUIST, M.D.*
Minneapolis, Minnesota

Although some individuals are prone to suicidal acts, it should initially be noted that the suicidal act itself may occur with multiple types of psychiatric diagnoses, or without any specific type. Degrees of depression vary from "depressive neurosis" to those of more psychotic proportions, such as manic-depressive illness, or "involutional melancholia," in which the suicide potential was once at a level where 25 percent of the patients died by their own hand.[3] Schizophrenic individuals may also manifest suicidal tendencies, particularly when they have prominent mood disturbances or delusional thoughts.

A further distinction is sometimes made between a genuine suicide attempt and a suicidal gesture. An operational definition of suicide would define it as "an act of self-destruction." It is an ultimate expression of the "acting out" of unconscious, self-destructive tendencies where the self is the object-victim. A suicide then combines an unconscious urge to kill, a desire to die, and also a wish to be killed; all are achieved in a "successfull" suicide.[6] Psychodynamically, a suicide externally expresses the intrapsychic hostile-aggressive forces *towards* the self which are literally and murderously acted out *against* the self.

The incidence of suicide is considered to be grossly underestimated by at least five to twenty times the reported figures. In 1964 the figure was 20,588.[2] Another interesting fact is that suicide is 2.5 times as frequent as homicide in the U. S. There are twelve times as many deaths by suicide as from aircraft accidents, a statistic which led someone to conclude facetiously that air travel is less hazardous than suicide. Suicide is ranked number five as the cause of death for white males between the ages of 15 and 44 years, and the incidence at age 50 is six times that at age 20. Below the age of 15 suicide is relatively rare; however, in both the 15 to 19, and the 20 to 24-year age groups, suicide is the fourth leading cause of death—

---

*Institute of Child Development and the Department of Psychology, University of Minnesota, and Psychiatric Consultant to the District Courts of Hennepin County.

after accidents, neoplasms, and homicide, with 600 deaths occurring annually in the two categories. Three of these four leading causes of death in these young age groups are seen to be related to problems in the realm of aggression. There are also over 100 suicides per year reported between the ages of 10 and 15, and about 10 per year under the age of 10.[9]

Descriptive Features in the Suicidally-Prone Individual

There are various types of clinical signs and symptoms to be kept in mind when the possibility of suicide is present. The first is evidence of a severe depressive mood state. Although there are "smiling" depressions, sadness in the patient is one of the best clues to a depressive state. Accompanying such a mood are references to discouragement, disillusionment, and disappointment. Disappointment includes reactions to frustrations and losses which may be peculiar to the individual, but are nevertheless significant for him, such as the loss of a job or other indices of his inadequacy, varying from social disappointments to sexual failures and impotencies. It is not true that a suicidal threat or gesture can be ignored or regarded as a "bluff." Preoccupation with thoughts of suicide is always in itself a disturbing sign of emotional conflict and an indication for appraisal.

The following are listed as indices of suicide potentiality; the more indices present, the higher the risk.

Early Morning Awakening

There may be a persistent pattern of early morning awakening, one to three hours earlier than the *previous* pattern for the individual, accompanied by a depressive mood.

Difficulty "Getting Going"

There is often difficulty "getting going," especially in the morning, with the individual feeling somewhat less depressed by late afternoon. He may report that he needs to "push" himself much more to get things done and that he feels more fatigued, although doing less. Increased irritability and indecisiveness add to this picture.

Lack of Interest

Lack of interest in things that were previously of great interest is another sign of the individual's inability to function in his customary manner. The greater the degree of this interest loss, the greater the suicidal potential.

Abrupt Improvement

An abrupt improvement for someone who has been seriously suicidal or depressed should be taken seriously, since this is the most dangerous time for a suicide attempt to occur. It is hypothesized that in the depths of a depression the individual is unable to mobilize himself sufficiently to carry out the suicidal act; hence, when his spirits suddenly improve, he has a much greater potential. It is as though he has suddenly come to a "solution" whereby he may solve his problems via a decision to take his life and end it all.

Progressive Withdrawal

A progressive pattern of withdrawal is related to a lack of interest, but also refers to an individual's losing contact with those to whom he has previously been attached. The greater the degree of such withdrawal, the more apt are the "signals" to be missed in an individual who is becoming deeply suicidal.

Inability to Verbalize

The less an individual is able to verbalize about his depression, the greater the suicidal risk. The nadir of despair is reached when he no longer feels it worthwhile to communicate that despair to others, resulting in his feeling progressively more and more isolated.

Sadness and Loneliness

The essence of a depression is a mood characterized by enduring feelings of sadness and loneliness. These may vary in degree from transient periods of feeling "blue" to profound despair wherein a sense of deep pessimism prevails since the future seems hopeless. Patterns of reiterating how deeply guilty and worthless one is, contrary to any objective external standard, may often be of delusional proportions, and are seen in depressions of psychotic dimensions. Delusions need not be confined to schizophrenia; a variety of them may be noted in severe depressions as well. A few types will be noted. One is the *somatic,* wherein there is a persistent belief that something is physically wrong, despite the absence of physical findings. In some cases there are physiological changes, such as abdominal pains, constipation, or bad breath. In severe cases, the delusions become so extreme as to include "intestines rotting," a head filled with cement, etc.

Nihilistic delusions* are similar but are externalized rather than confined to the body. There may be a persistent belief that a terrible disaster is inevitably going to occur, that the world is about to disappear, etc. Signs and expressions of not liking oneself may expand in a psychotic process to profound accusations of self-worthlessness out of proportion to any misconduct. Delusional *guilt* may be an accompaniment and expresses not only anticipation of punishment but a conviction of its desirability. The above may all lead to feelings of change in one's body or environment.

In these cases reassurance rarely has any significant effect. Giving these individuals "pep talks" or attempting to "talk them into" enjoying life rarely has more than a temporary effect. It may actually make them more depressed in some cases since it engenders a view that they are failing others' expectations of them as well as their own.

Psychodynamic Patterns in Suicide

In addition to the external features previously noted, there are motivational forces present. Herein lies the distinction between the *descriptive* and the *dynamic* aspects of psychiatry. The dynamics encompass various conflicting forces within an individual personality, coupled with some of the predisposing background factors which include his psychological and social development. The psychodynamic factors in a suicidal individual are concerned with some of the intricacies within him which lead him to contemplate suicide.

To formulate dynamics we must keep in mind the significant *details* of a suicidal act, the *method or technique* contemplated, as well as the *circumstances* which may induce an attempt.[4] As clinical examples of *details*, we may think of the case of a 45-year-old woman who, after receiving a letter that her son has been killed in the Armed Forces, jumps out of a window a month later with a picture of her son tucked inside of her dress, with the inscription: "Bobby, I'll see you soon." Another example is that of a 60-year-old man who is informed that he has cancer but fails to reveal the fact to his family. He commits a genuine suicidal act to "save" his family from having to see him die a long, painful death.

The *method* of suicide is important since it reveals information regarding the personality integration and functioning of an individual. We thus learn whether there have been multiple suicide attempts previously, whether they have been carried out in a planned, methodical manner, and whether there have been chaotic attempts which have miscarried. Several questions are relevant here. It is important to learn the patient's attitude toward death and what he thinks will follow death or a "successful suicide attempt," as well as his thoughts at the time of planning such an act, either then or at the time of any previous attempts. For example, "What were you thinking at the time you took the 20 seconal tablets?"

There are various psychodynamic constellations to be noted, with the warning that a patient cannot be automatically categorized; rather the individual conflicts and circumstances must be delineated in each separate case in order to reconstruct the motivations.

Getting Even

One type of psychodynamic formulation may be considered under the heading of "death as a getting-even maneuver." Let us consider the situation of a particular 17-year-old boy who has been rejected from a college which he has long been hoping to attend. His response is to shoot himself, in the conviction that he will actually die. The dynamics here consist of attaining an illusory control over the people and the situation which have rejected him. He is now the one in power. Such individuals visualize the suffering their demise will cause others, e.g., how their relatives will react when they see them lying in a coffin. This type of theme is frequently noted in adolescents in whom there is a prominent element of self-pity.

Gaining Power via Death

There is a second and related dynamic formulation which involves the "gaining of power via death." In this situation the individual attempting suicide has the ultimate control of deciding if he wishes to live or not, rather than leaving his life and fortunes at the disposal of others to decide. It is an effort to negate a feeling of being the helpless victim of others' decisions. In some cases it may take the form of outwitting fate.

---

*See Test Your Word Score Page 1637.

Retroflexed Homicide

A third possibility is that of suicide as a "retroflexed homicide:" an inverted homicide, which Freud discussed in a 1917 paper, "Mourning and Melancholia."[5] An example is the wife of a middle-aged man who has been having an affair outside his marriage for five years. When she becomes aware of the situation and confronts him with making a choice, he decides to leave her for his paramour. At that point his wife attempts suicide. The dynamic meaning for this lady is to self-punitively act out her anger in an act of *self*-destruction in contrast to destroying her husband and/or his girl friend. The message is also, "Look what you have done." Some theorists maintain that this motive, along with other factors, is present in almost every suicide.

Reunion

A fourth theme is that of accomplishing a "reunion." In this type of situation the act of dying is used in an effort to reinstate a close relationship which had previously existed, such as with an individual now dead. The emphasis here is not on dying itself, but rather on the hoped-for reunion which is to follow. Consequently, in these cases there is often a pleasurable feeling, which can be noted in interviews with an individual as he talks nostalgically about his longings. Marked dependency needs are conspicuous in these people, particularly as directed towards parental figures or members of the family who have "deserted" them, by such acts as death, abandonment, or threatened divorce. An example would be a 35-year-old man whose wife had been killed in a car accident six months earlier and who finds himself repeatedly driving at 80 and 90 miles an hour on slippery highways. This behavior finally culminates in an almost fatal accident. The topic of "accident proneness" is relevant here. Another variation is the form of chronic suicide seen in alcoholism or addiction. A woman of 50 whose husband dies succeeds in becoming an alcoholic in a few years with all its concomitant self-destructive aspects.

Rebirth

"Death as a rebirth" is a fifth and related theme. This involves wishes to "start over" and is frequently verbalized to a physician once a relationship is established. It may be related to some loss or frustrating situation which the individual desires to "wipe out," such as a past misfortune or disappointment. Again, as with some of the other types noted, this is not really an effort to die, since the wish is to continue living but in a new form. It is a "death and transfiguration" theme. The magical or wish-fulfilling element is strikingly present with the denial of death as something permanent.

Self-punishment

A sixth formulation is that of suicide as self-punishment. This may be related to various themes where an individual regards himself as having failed and feels that a situation is irremediable. Such individuals often have exceedingly high and rigid standards for themselves: what we more technically term a "strict superego," with associated compulsive features. While this may account for the higher rate of suicide among physicians and certain professional groups than among the general population, it does not account for variations within the groups. The over-all annual rate for physicians has been estimated at 36 per 100,000, three times that of the general population.[1] However, among specialists there is a variation from a low of 10 per 100,000 for pediatricians to a high of 61 per 100,000 for psychiatrists if we presume the reporting to be accurate. When individuals with high standards fail to live up to those standards, an enormous amount of self-hatred is released. These individuals have a particularly predisposing background of depression-proneness in their personality.

In the past history there may be episodes when their aggression was externally directed, so that they are not aware of the depressive component within themselves. In extreme cases there may have been an integration on a paranoid level which succeeded in keeping their depression in abeyance. A variation of the self-punishment theme is a suicidal act with an element of atonement. Self-punishment has the added element of relieving one of guilt in the form of an expiation. Following a genuine suicidal effort, there is atonement for the failures, and the depression temporarily lifts. This is often surprising to some clinicians who cannot understand how an individual who has just done such an act can subsequently appear so tranquil and intact.

Schizophrenic Process

A more exotic suicide is seen in an individual who views himself as already dead even before the act of suicide. These individuals are often schizophrenic. They describe themselves as having already died or as feeling emotionally dead and detached. One is impressed by their flatness and lack of emotion. Death is viewed as a release from the suffering of life; suicide is merely putting the finishing touches on an event that has already occurred in their fantasies. One young adolescent lay in bed most of the day, after surviving a suicide attempt, with a cloth over his face, asserting that he was dead. This type of manifestation is part of the larger picture of the schizophrenic process.

Götterdämmerung

A wit once said: "Suicide is still a fatal disease." This is true for the acute attempt if successful, but it is just as true for more insidious acts which eventually culminate in self-harm. The varieties of behavior that can be described as small acts of self-destruction are almost limitless and include neglect of one's physical health, excessive types of risk-taking, and any self-defeating behavior in which strong, unconscious determinants lead an individual to destroy either those close to him or something to which he was once dedicated, such as a social goal, a reputation, a business, or a profession. In the latter case, the destruction may have dramatic overtones, such as a combined homicide-suicide (*a Götterdämmerung*), but it more frequently takes the form of undermining personal relationships, within a family or among a group of people. The concealment of strong paranoid and sadistic tendencies then becomes more evident, although it may not be noted until the long-range consequences of an individual's life are viewed in retrospect.

These various psychodynamic themes have alluded to the interpersonal elements involved in any suicidal act. These types of interactions are often present within a family unit, or among other individuals with whom a person is in contact prior to his suicidal act. In addition, interacting factors from the past seem to "live on" as though in a state of perpetual readiness and, under precipitating stresses, play an active part in any given suicidal act. Conveying covert or unconscious destructive wishes to another person is one of the more cogent forces operating in any type of acting-out behavior. Suicide and homicide are merely a sub-class of such communication of wishes. The following case illustrates this type of pattern.

A 28-year-old divorced, white male was found dead by hanging in an institutional setting. There had been a history of one suicide attempt previously for which he had been given electro-shock treatment, with several depressive episodes prior to his death. His behavior alternated between various forms of self-destruction activities, such as exhibitionism, for which he had been apprehended several times. During his institutional stay, his widowed mother had visited him several times and noted him to be deeply unhappy. After his suicide she related that during these visits she had begun to pray earnestly every night that if her son could not live outside an institution, God should release him by death from the burden of so living. Shortly after one discharge, he was again committed for similar behavior, and faced a long detention period. The mother's feelings were reinforced by her being told that no treatment was available for her son's condition. Realizing her own wish that her son not have to spend most of his life institutionalized, she literally conveyed this wish to him. At that time he agreed with her that such a meaningless existence would not be worth the effort. It was shortly thereafter that he was found dead. Related background factors operating in this materialization of a death wish have been omitted for brevity. It should be noted that in no way was the mother operating with a conscious wish to kill her son. It was rather the derivative, yet fully potent wish, which was transmitted and acted upon.

"Gestures"

"Gestures" are often distinguished from what are referred to as genuine "attempts." Such a dichotomy* introduces all types of fallacies, such as: "Even fakers have accidents." This undoubtedly does happen, but more important is the failure to understand the personal and social factors leading to such behavior. Characteristic of a gesture is an act which appears to have a self-destructive theme, but in which the observer can perceive a self-limiting quality such as, "He really didn't want to die." The examples vary from taking insufficient quantities of pills to engaging in risk-taking behavior after notifying someone with whom the "faker" is involved or to whom he is attached, or in wrist cutting. A host of responses may then arise in the clinician, varying from outright anger and rejection to a personal involvement amounting to a persistent type of rescue operation.[8] This is especially so if the perpetrator is an attractive and dependency-evoking female in the adolescent or young adult stage. A type of intense attachment with open displays of covert hostility is then reenacted—often with a succession of professional people in schools, agencies, clinics, and hospitals. Diagnostic labels become attached in transit, including "psychopath" (especially by older staff), "schizophrenia" (by middle-aged staff who are aware of the covert manifestations of ambulatory schizophrenia), "hysteria" (by young male staff), and "normal" (by those who see such gesturing behavior as a response to a disturbing environment and who are prone to label behavior as socially-determined).

---

*See Test Your Word Score Page 1637.

There are often precipitating factors in such situations, such as a disorganized family structure, a background within the family where sensual and aggressive impulses were openly displayed with only a modicum of controls, alternations between indulgence coupled with unpredictable condemnation, and punishment for "acting so disgracefully." The primary defenses operating, besides acting out, appear to be a projection of problems on to others, as well as externalizing them, so that difficulties are viewed as impinging from outside sources rather than as self-imposed. Escapades of a sexual or drug-induced type have often been tried, as well as involvement in multiple efforts to make therapeutic contacts via group activities.

A "gesture" appears to be a reaction to frustration when these "outs" are either not available or have lost their vitality and appeal. The gesture then has a variety of meanings. It is not only attention-getting for secondary gain, but reinstates a dependency relationship where "somebody cares." It is simultaneously a direct form of impulse discharge, thus accounting for the observed relief or state of relaxation frequently following it. For some this is equivalent to a self-punitive purification process like any token of suffering. The anlage* is seen in young children who transgress and then ask to be punished or hit themselves. Acting-out gestures serve to avoid dealing with personal feelings and conflicts, since they are rather "put into action" instead. In the more disturbed, certain self-mutilative acts may accompany more bizarre trance states where altered consciousness may be present. These efforts may be not so much gestures as part of a ritualized delusional system.

Summary

Some of the more acute indicia of severe depression are handled on the basis of the *descriptive features* that are detectable from a clinical evaluation, and the *psychodynamic patterns* which deal with the conflicts and motivations with which an individual is struggling. The faces of depression, as well as of psychoses, are often masked, and exert profound effects not only on the individual but on all those with whom he comes in contact.

Ideals are to run races with. The moment we stop chasing them they sit down and become opinions.—Lutheran.

|| Thrombocytosis

A Clinical Evaluation of 322 Patients

STEPHEN E. SILVIS, M.D.*
NEJAT TURKBAS, M.D.†
WILLIAM R. SWAIM, M.D.‡
ALFRED DOSCHERHOLMEN, M.D., Ph.D.#
Minneapolis, Minnesota

THROMBOCYTES WERE THE last of the cellular elements of the blood to be recognized, probably by Bizzozero[1] in 1882. They are still the most poorly studied of the formed elements in the blood. Many of the studies showing thrombocytosis associated with various pathological conditions were done at a time when indirect counting techniques were in use. Because of the poor reliability of these methods[2] and the fact that the mechanism of thrombocytosis in any given situation is not well understood, most of this early information has been ignored. However, recent investigators[3-5] have suggested a humoral mechanism for maintenance of normal platelet levels, and an excess of this humoral substance in disease states results in thrombocytosis.

The purpose of this paper is to call attention to the principle conditions in which elevated platelet counts are found. It also reemphasizes the need for a thorough evaluation of patients with thrombocytosis.

Materials

Records of the hematology laboratory at the Minneapolis Veterans Hospital, Minneapolis, Minnesota, for the period of one year were reviewed. Charts of the patients with platelet counts above 350,000/mm^3 of blood were studied. The highest platelet count in the clinical record was used in this study. The hemoglobin level at the time of the peak platelet count was also recorded. Evidence of thrombosis was obtained from review of the clinical records and autopsy reports if available. There were 12,557 hospital admissions during the year the study was undertaken.

Method

The platelet count was done by the modified Rees-Ecker technique[6,7] with an ordinary light microscope.

The mean normal platelet count in this laboratory for males is 240,460 per mm^3 plus or minus two standard deviations of 93,707 (N=39) with a 95 per cent range of 146,000 to 335,000 per mm.[3] These values compare with a mean of 258,000 and a 95 per cent range of 130,000 to 380,000 (N–180) reported by Miale[8] and a narrower 95 per cent range than that of Brecher, Schneiderman, and Cronkite (140,000 to 440,000).[9]

Results

Three hundred and thirty-nine patients with platelet counts above 350,000 were found. This number represented a 2.57 per cent incidence of thrombocytosis when compared with the total number of hospital admissions. It must be pointed out that platelet counts were not done on every patient admitted to the hospital. Therefore the study cannot answer the question of true incidence, but it does allow an analysis of the kinds of disease associated with elevated platelet counts. The records of 17 of these patients were unobtainable. From the 322 records available, it was found that 206 patients had malignant disease and that 116 had benign diseases. Table 1 shows the malignant conditions associated with thrombocytosis.

Table 2 shows the cases of thrombocytosis associated with various benign diseases.

There were 38 cases with thromboembolic disease in the 322 cases studied. Thirty-two of the patients suffered from this complication after the thrombocytosis was discovered, while six had had thromboembolism in the past.

The average platelet counts with and without recent thrombosis were 539,000 and 497,000 respectively. Upon application of Student's "t" test the difference between these two values was not statistically significant ($0.1<p<0.2$); 9.9 per cent of the patients in this study developed thrombosis. When the platelet count was above 500,000, 11.5 per cent of the patients developed thrombosis, and when the platelet count was below 500,000, 8.9 per cent developed this complication. Table 3 summarizes the types of thromboembolism observed. The 32 patients with recent thrombosis had a total

Cerebrovascular accident	8
Myocardial infarction	3
Other arterial thromboses	2

of 35 thromboembolic episodes. Twenty-five of the patients with thrombosis had malignant disease.

Of the 322 patients in this study, 88 (27.3 per cent) had a normal hemoglobin, i.e., above 14 grams per 100 ml. The Figure shows the hemoglobin concentrations in patients with and without thromboembolic disease. The average hemoglobin concentration in the group which developed thromboembolism was 13.6 grams per 100 ml, while the average hemoglobin concentrations of the group who did not develop this complication was 12.2 grams per 100 ml. When applying Student's "t" test, the difference between the average hemoglobin concentrations in patients with and without thrombosis was statistically significant ($p < 0.01$). In other words, the patients with thromboembolic complications had a significantly higher hemoglobin concentration.

The correlation between the hemoglobin concentration and platelet count in the entire series was investigated, and no significant correlation was found ($r = 0.0000$).

Discussion

Physiology

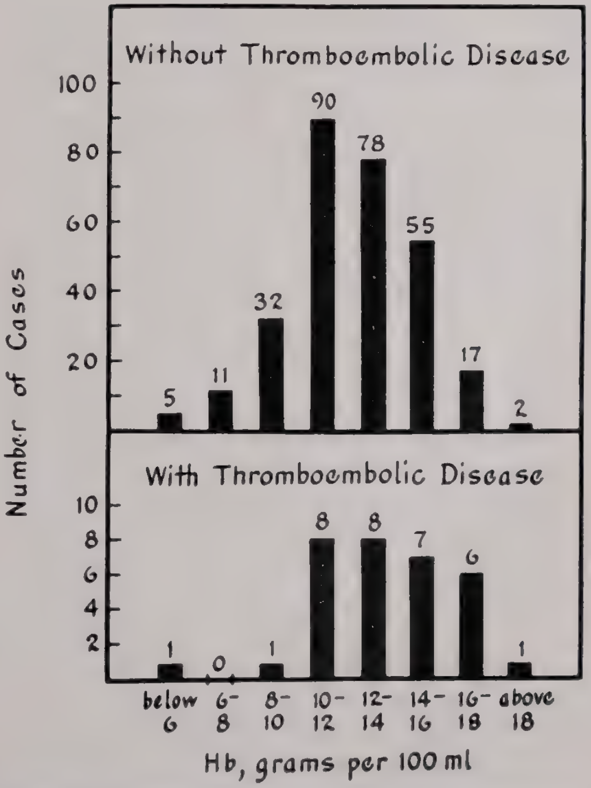
The physiological regulation of platelet production may include a humoral mechanism. Thus, under appropriate conditions plasma from both animals[5,10] and man[3-5,11-13] is capable of stimulating platelet production. Deficiency of platelet-stimulating plasma factor has been described in a child with congenital thrombocytopenia.* Increased amounts of platelet-stimulating plasma factor has been observed in animals made thrombocytopenic with platelet antisera.[10] In conditions with a temporary thrombocytopenia increased amounts of platelet-stimulating plasma factor have been recorded immediately before the rise in the platelets.[5]

Thrombocytosis in Malignant Disease

The most surprising result of this study was the high frequency of malignant disease among the patients with increased platelet counts. The association of thrombocytosis and cancer was first described by Riess in 1872.[14] Although at that time platelets were not considered cellular elements, this association was later confirmed by Hayem[15] in 1889. Subsequently, many investigators have found thrombocytosis in patients with various tumors.[16-24] The concept that the platelet counts fall in the late stages of tumor development is supported by occasional reports of thrombocytopenia in cancers.[25-28] Qualitative changes in the platelets have also been described in patients with malignancy.[22,23,29-31]

The mechanism of the thrombocytosis associated with cancer is not understood. It is not clear whether the thrombocytosis is related directly to an effect of the tumor or to some secondary effect, i.e., the anemia. It is unlikely that it is due entirely to the anemia as suggested by Noeff[19] because it appears in patients who are not anemic, and there is no statistical correlation between the hemoglobin concentration and the platelet count in the present study. Furthermore, thrombocytosis occurs with a high frequency in patients with tumors where bleeding is unusual, i.e., carcinoma of the lung.

The mechanism of thrombocytosis could be due to increased production of platelets or to a decreased rate of removal of circulating platelets. To our knowledge no studies have



Figure—Frequency of hemoglobin distribution in patients with and without thromboembolic disease.

---

*See Test Your Word Score Page 1637.

been done which show prolonged survival of platelets in the circulation. Increased production of platelets could be due to increased activity of pre-existing megakaryocytes or to an increased number of megakaryocytes. Numerous workers[23,33-35] have shown an increase in the number of megakaryocytes in the bone marrow of cancer patients. Hueper[32] reported such an increase in spontaneous mammary cancers in mice. The present evidence would suggest over-production of platelets in malignancy.

Fanger, Cella and Litchman[36] reported two cases of cancer in a series of 28 cases of thrombocythemia; they postulated that the platelet elevation might be due to tumor necrosis. We have observed marked fluctuation in platelet counts but have been unable to correlate these with changes in tumor activity. There is no consistent rise in the platelet count with tumor necrosis from x-ray or chemotherapy. However, it is recognized that irradiation or chemotherapy suppresses the bone marrow response.

Thromboembolism

It is generally believed that there is an increase in the incidence of thromboembolic disease among patients with carcinoma. This increase has been somewhat difficult to define because the cancer patients frequently have other factors, i.e., inactivity, debility, surgery, and prolonged bed rest, which are known to be associated with an increased incidence of thromboembolic disease. This disease is frequently observed in patients with carcinoma of the pancreas. Gullick[37] reported 17 cases of thrombophlebitis in 68 cases of carcinoma of the pancreas. Thrombophlebitis may be the presenting symptom in patients with carcinoma of the lung.[38] Sproul[39] found a 2.5 percent incidence of venous thrombosis in patients with carcinoma of the lung.

In the present study the difference between the average platelet counts in patients with and without thrombosis was not statistically significant, a fact which may be due to the skewed frequency distribution of our data.[40] However, it should be remembered that only cases with platelet counts above the normal range were included in this series.

The question arose whether the hemoglobin concentration also might be a factor in the development of thrombosis. A statistically significant direct correlation between hemoglobin concentration and thromboembolic complications has been described in this paper. This concept is supported by Nordoy[41] in his experimental studies in rats.

Thrombocytosis in Acute Blood Loss and Iron Deficiency

Acute bleeding and chronic iron deficiency was documented in 32 patients with thrombocytosis in this study. It is well known that acute bleeding is followed by thrombocytosis.[42,43] It is less well known, however, that thrombocytopenia may precede this thrombocytosis. Thus, Desforges, Bigelow, and Chalmers,[42] studying acute gastrointestinal bleeding, found that the platelet count fell during the bleeding and that it subsequently rose, frequently to levels above normal in the convalescent period, reaching a peak seven to 14 days after the bleeding episode. Numerous workers[2,14,15,44-46] have called attention to elevated platelet counts accompanying chronic iron deficiency anemia with and without hemorrhage. The elevated platelet counts returned to normal following treatment of the iron deficiency.[45,46]

Surgery and Splenectomy

Several investigators[47,48] have demonstrated changes in the platelet count following surgery, similar to those seen after an acute bleeding episode. These changes are apparently not related to the degree of blood loss. The thrombocytosis is more prolonged and more pronounced after splenectomy.[2,49] One of the patients in this study had platelet counts ranging from 400,000 to 600,000/mm^3 20 years after splenectomy.

Rheumatoid Arthritis

Ten patients in this study with rheumatoid arthritis showed elevated platelet counts, a finding also noted by Levin and Conley.[24] Iron deficiency is quite common in this illness and may contribute to the thrombocytosis.[50]

Alcoholism and Cirrhosis

The usual problem encountered in patients with chronic alcoholism and cirrhosis is thrombocytopenia. In this study there were 12 patients with elevated platelet counts associated with cirrhosis or chronic alcoholism. Reasons for these elevations cannot be determined from the present study; however, three possible explanations should be considered. It is known from the work of Herbert[51] that thrombocytosis may occur in response to dietary folic acid. Since patients with alcoholism and cirrhosis of the liver frequently have folic acid deficiency,[52] response to this substance in the normal hospital diet may account for the observed thrombocytosis in some patients. Rebound thrombocytosis following thrombocytopenia may also occur on withdrawal from alcohol.[53] Another possibility is a subclinical iron deficiency of these subjects.

Pernicious Anemia

The thrombocytosis of pernicious anemia which occurs in response to specific therapy is also a well known phenomenon[54] and was observed in five patients. "Spontaneous remission" of pernicious anemia has also been associated with thrombocytosis.[18]

Infections

Several investigators[14-18] have found elevated platelet counts in patients with acute and chronic infection, especially tuberculosis. The mechanism of the thrombocytosis in these instances is not understood. It is not always associated with anemia. Port and Akiyama[17] observed a fall in the platelets during acute infection with a subsequent rise, frequently to a level above normal, following the crisis.

Miscellaneous Benign Condition

In most instances, these patients had only a single platelet count performed and no further evaluation was undertaken. It was this lack of further study that probably prevented us from placing these cases in a defined category.

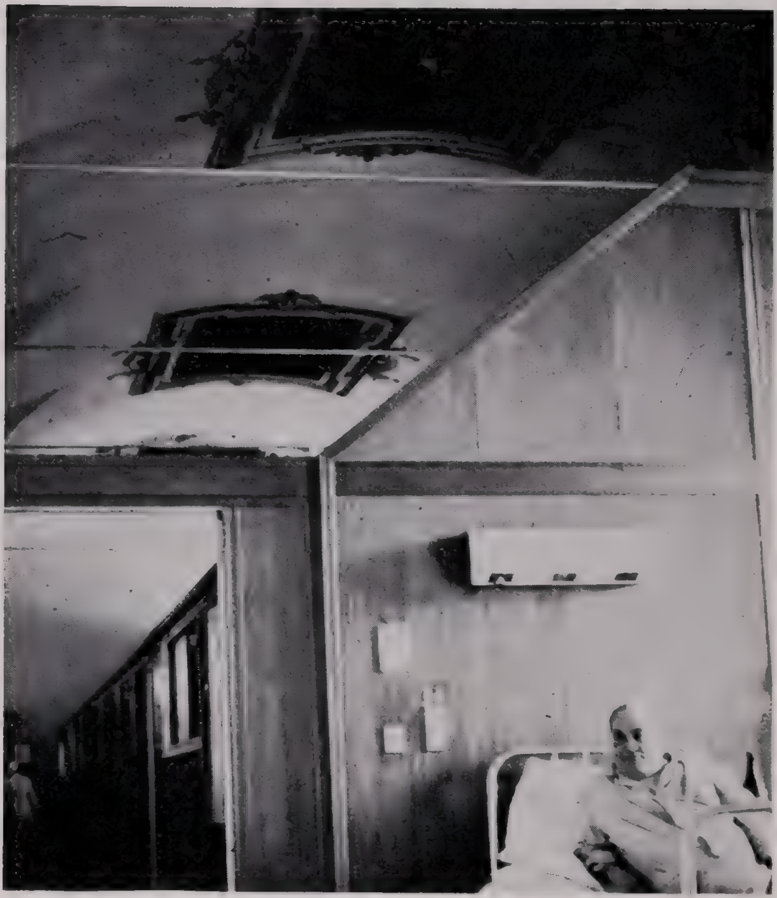
Thought

It was the habit of Immanuel Kant, famous German philosopher, to rise in the morning at five o'clock and think for two hours. He had no apparatus; there was nothing in his hands. He sat and thought; he did not just sit.—William Lyon Phelps.

Old Hospitals



Ospedale Fatebenefratelli, Rome

The Brothers of the Order of St. John of God faced an unusual problem when they modernized the ancient Hospital of St. John Calibita in Rome. The hospital, founded in 1575, is the headquarters of the order which operates 240 hospitals around the world. Its high-ceilinged Great Hall of the Sick was a model facility in the fifteen hundreds, but appealed little to twentieth-century patients who demanded more privacy than could be provided within its great expanse. The government decreed that the building was of historic and artistic significance and that its external appearance could not be changed. Furthermore, the Brothers were forbidden to add a second story inside the building or in any way to alter or obscure the venerable paintings which decorated the ceiling. Their imaginative architectural solution was the maze of paneled enclosures shown above. Each compartment accommodates five patients and is open at the top, affording a view of the ancient decorated ceiling. The sanctuary at the end of the church-like Great Hall has been converted into a television lounge.

Newer additions to the 280-bed voluntary hospital house departments of cobalt therapy, diagnostic isotopes, angiography and inhalation therapy. Most patients are covered by health insurance, and room rates for a five-bed room are 3000 lire ($4.80) per day. The Brothers' nickname, "do-good brothers", accounts for the popular name of the hospital which is Ospedale Fatebenefratelli.

Tussive Syncope

JUDAH L. SKOLNICK, M.D.*
DAVID E DINES, M.D.†
Rochester, Minnesota

Tussive syncope is a loss of consciousness following an episode of coughing. Synonyms for this syndrome are "cough syncope" and "laryngeal vertigo."[1,2]

Credit for the first reported case of tussive syncope goes to Jean Martin Charcot, who presented two cases in November 1876; but much earlier Sydenham and Heberden described cases which may well have been examples of tussive syncope.[1,3,4]

Observations on Mayo Clinic Cases

Tussive syncope was diagnosed in 18 patients (16 males and two females) at the Mayo Clinic from 1950 to 1967. The patients' ages varied from 16 to 75 years with a mean age of 52 years. Twelve were cigarette smokers who smoked one to three packs per day and had a chronic, productive cough, with the syncopal spells occurring with paroxysms of coughing.

One of the six patients with no history of smoking had undergone resection for tuberculosis; he continued to have a chronic nonproductive cough related to empyema. Five of the patients who did not smoke had chronic asthmatic bronchitis with paroxysms of coughing associated with wheezing; eight gave a history of excessive intake of ethanol.

Tussive syncopal spells varied from 30 days to four years and lasted from 30 seconds to three minutes. Fourteen patients were obese; the body build of four was normal. Four patients appeared plethoric; 10 had inspiratory and expiratory wheezes and expiratory slowing. Three of the 18 patients had diffuse atherosclerotic changes, severest in the aortoiliac system.

Neurologic testing of 17 patients gave normal results.

Bronchoscopy showed chronic bronchitis in five patients, a deformity in the right mainstem bronchus in the patient who had undergone resection for tuberculosis, an obstructing

*Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Internal Medicine.

†Mayo Clinic and Mayo Foundation: Section of Medicine.

carcinoma in one patient, and normal findings in the remaining 11 patients.

Roentgenograms of the thorax showed evidence of mediastinal widening from lymphoma in three patients, obstructive pneumonitis with a hilar mass in two, changes compatible with emphysema in two, and empyema in one patient; those of the other eight patients did not show any evidence of abnormality.

Electroencephalograms were made for eight of the 18 patients but were helpful only in a negative sense in that they excluded disease of the central nervous system as a cause of the syncopal spells. Only one of the 18 patients was polycythemic.*

Pulmonary function tests were performed in seven of the 18 patients; they demonstrated an obstructive pattern in six patients and a normal pulmonary function in one patient. Pulmonary function in one case is demonstrated (Tables 1 and 2), showing a mild obstruction component as well as a greater-than-normal pulmonary resistance and maximal expiratory pressure.

Clinical Characteristics of the Syndrome

The syndrome of tussive syncope occurs predominantly in men, and in one series, 97% of the patients were males. In this series, the syndrome occurred most frequently among patients between the ages of 35 and 60 years, with the peak incidence occurring in the 40s.[1]

Respiratory Disorders

The typical patient frequently has a mild chronic respiratory disorder, the commonest disorders being chronic bronchitis, emphysema, and bronchial asthma. He is obese, of heavy musculature with a large chest, plethoric, robust, and a creature of excesses. Usually he has a history of excessive smoking and excessive ingestion of alcohol. Attacks frequently occur during eating, drinking, or laughing.

Orthostatic Effect

Position tends to affect the occurrence of syncope; therefore attacks occur most frequently when the patient is in a standing position, although they may occur in any position. The cough is typically dry, paroxysmal, and nonproductive. Patients may frequently be hypertensive and have evidence of peripheral vascular disease. In scattered reports the syndrome has been associated with gout and other rheumatic symptoms.[1,2,5]

Typical Attack[3]

The patient exhibits a coughing paroxysm and his face becomes congested. Several seconds after onset the eyes become fixed and vision becomes less acute with loss of peripheral vision; the patient is able to hear commands but is unable to respond. If cough ceases at this point, signs and symptoms do not progress; if cough continues, however, within a second or two the eyes turn upward, consciousness is lost, and the patient becomes flaccid. Cough ceases with the loss of consciousness.

The attack may rarely be accompanied by mild convulsions; but tongue biting and incontinence do not occur. If clonic twitchings develop, they occur about two seconds after the loss of consciousness and usually involve the orbicularis oris and hand muscles. Consciousness is regained within about 10 seconds. Duration of the attack is characteristically two to 10 seconds, but may be 30 seconds to one minute.[1,2]

Etiologic Aspects

The three types of etiologic mechanisms: hemodynamic, reflex, and "concussive" are thought to be operative in tussive syncope.[6] It is probable that any one of these three mechanisms, or any combination, may be responsible in any individual case.

Hemodynamic

Basic to each of these three mechanisms is a modified Valsalva maneuver. In performing a Valsalva maneuver, the glottis is voluntarily closed and a strong expiratory effort is made against the closed glottis. This action may produce an intrathoracic pressure in excess of 80 mm Hg. The pressure is reflected in a similar rise in the alveoli, blood vessels, and other structures in the thorax as well as increased intra-abdominal pressure caused by the action of the abdominal musculature.

The main hemodynamic effect of the Valsalva maneuver is impedance of the return of blood to the right side of the heart. Therefore, venous pressure in the head and extremities increases sharply, venous return decreases sharply, and cardiac output and arterial blood pressure also decrease. As a result of blood flow in the sino-aortic zones, the heart rate increases.

Vital capacity (inspiratory), L	4.82	4.3

As soon as expiratory effort is decreased, blood rushes into the right ventricle, which becomes enlarged and contracts forcibly to pump its contents through the pulmonary circulation and into the left side of the heart. The surge of blood into the left ventricle causes a sudden increase in the systemic blood volume along with a rise of arterial pressure. This action elicits, reflexly from the pressoreceptors, a brief period of bradycardia, after which the pre-Valsalva conditions are reestablished.[7-9]

Reflex Mechanism

The major reflex mechanisms proposed to contribute to the production of syncope are all mediated via the vagus nerve. Vasovagal syncope is an entity caused by sudden reflex loss of peripheral resistance with resultant vasodepression and cardio-inhibition.

The various receptors involved in vasovagal syncope are (1) the carotid sinus (cardio-inhibitory, vasodepressor, and central), (2) the aortic pressoreceptors, (3) the pulmonary vessel pressoreceptors with increased pressure in the pulmonary circuit which causes bradycardia and hypotension, (4) the coronary reflexes (chemoreceptors), (5) the intracardiac baroreceptors, and (6) the cerebral pressoreceptors. All these reflexes will cause bradycardia and hypotension.[1,20-26]

Concussive

Coughing consists of four phases:[10] (1) inspiration, (2) sudden violent contraction of abdominal and accessory respiratory muscles, (3) a forceful explosive expiration against a closed glottis, and (4) with either a single severe cough or paroxysm of cough, a prolonged inspiration with some degree of obstruction.

A single cough can increase intrathoracic pressure 20 to 30 mm Hg; a more vigorous cough can increase it to 100 mm Hg. The cough associated with syncope will generally produce a pressure of 150 to 300 mm Hg. Hemodynamic effects are proportionate to the violence and duration of coughing attacks.[11,12,13]

Physiologic Changes

The consequences[14] of the Valsalva maneuver or of the cough[14] that is capable of producing syncope are: (1) peripheral vasodilation, (2) pulmonary vasoconstriction, (3) decreased venous return, (4) reflex bradycardia, (5) collapse of veins at the entrance of the thorax, (6) anoxemia, and (7) cerebral "concussion."

In one of our patients a sinus tachycardia and slight rise in blood pressure developed consistently with each period of unconsciousness.

Increase in cerebrospinal fluid pressure is essentially the same as the increase in intrathoracic pressure.[3,15] Sometimes the intrathoracic and cerebrospinal fluid pressures approach 300 mm Hg. Myelograms taken during the Valsalva maneuver show that when intra-abdominal pressure increases, the subarachnoid space narrows and the nerve roots are displaced medially.[3] Therefore, the increased intrathoracic pressure produces an enlargement of the epidural space and an increase in spinal fluid pressure. The increase of epidural mass is thought to be the result of engorgement of epidural veins caused by displacement of blood from the abdomen and thorax. The movement of loose fatty and areolar tissue and nerve roots into the spinal canal may add to compression of the subarachnoid space. Increase of the intracavitary pressure associated with cough might mechanically "squeeze" blood from both arteries and veins in such cavities to regions not subjected to increased extravascular pressure. These regions would be the skin and muscles of the head, neck, and extremities. The brain is essentially "bloodless."

Net Intracavity Pressure

The crucial factor is "net" intracavitary pressure (that is, intrathoracic, intra-abdominal, and intracranial pressures), which is the peripheral arterial pressure minus the increase in intracavitary pressure. In people with tussive syncope, this can approach or equal zero. Intracavitary vessels collapse and cerebral anoxia and syncope occur.[16] Females apparently can seldom cough forcefully enough to reach such pressures, which accounts for the greater incidence of tussive syncope among males.

Blood is "squeezed" from the cranium by the jugular veins and anastomotic channels of the diploic, emissary, and ophthalmic veins. A rich anastomosis exists between the intradural and the extradural veins. The rich venous plexus, including vertebral veins, serves as a reservoir to help maintain equilibrium between changes of pressure of cerebrospinal fluid and the cerebrovascular system. An increased cerebrospinal fluid pressure would result in an expulsion of blood from intracranial vessels to that part of the reservoir not subject to a similar rise in pressure.[3]

Increased Cerebrospinal Fluid

Another proposed central nervous system mechanism, more directly representing concussion, has to do with a sudden depolarization of cerebral cells due to increased cerebrospinal fluid pressure. However, certain investigators feel that the necessary elevated and sustained pressures are not feasible because of the vascular anastomotic channels that may act as escape valves.[17-19]

Emphysema

Emphysematous patients seem to have several predisposing factors for syncope.[27] Their alveolar pressure is greater than normal, and hence an even higher pressure may develop during coughing. They also have greater variations of intrapleural pressure. The increased rigidity of peripheral alveoli that accompanies the early loss of elasticity prevents full transmission of pressure from within the tracheobronchial tree to the pleural spaces, setting up a pressure gradient. The alveoli of these patients have an oxygen content lower than normal.[1,27]

Tussive syncope rarely develops in patients with large quantities of sputum. For some reason their intrathoracic pressure rarely exceeds 100 mm Hg.

Electroencephalographic changes may occur during cough syncope. The commoner patterns are slowing of dominant rhythms, increase in amplitude, and several seconds of electric silence.[16,28]

A recent report[29] on 14 patients with tussive syncope showed that half of them had demonstrable cerebrovascular disease. Poor cerebral circulation would serve to amplify the previously mentioned hemodynamic effects of forceful cough.[30]

Tussive syncope is more likely to develop in obese patients than in those of normal weight because obese patients have a low intra-abdominal pressure and, therefore, less blood flow from the abdomen to the chest.[7]

Summary

The basic mechanism of tussive syncope probably is a combination of decreased cardiac output, hypotension, decreased cerebral blood flow, and anoxia. Variable roles may be played by vasovagal reflexes, hyperventilation, and neuronal depolarization.

The mechanism must vary in different individuals as shown in one of our patients who consistently had tachycardia with slight elevation in blood pressure during repeated episodes of unconsciousness.

Tussive syncope is usually a self-limited, benign disorder. Treatment includes stopping smoking and drinking alcohol, and correction of obesity. An attempt may be made to suppress coughing and to liquefy secretions with high intake of fluids.

Never do a wrong thing to make a friend or to keep one.—Robert E. Lee.

Edward Gibbon's Hydrocele

For many years it has been taught—I have taught it myself to generations of students—that Gibbon's hydrocele surpassed in greatness all other hydroceles, that it contained twelve pints of fluid, and that it was, in short, one of those monstrous things which exist mainly in romance.

What do we really know about it?

The first hint of trouble given by the hydrocele occurs in a letter by Gibbon to his friend Lord Sheffield. It is so delicious, so typical of the eighteenth century that I cannot resist re-telling it. Two days before, he has hinted to his friend that he was rather unwell; now he modestly draws the veil. "Have you never observed, through my inexpressibles, a large prominency circa genitalia, which, as it was not very painful and very little troublesome, I had strangely neglected for many years?"

Gibbon had been staying at the Sheffield House in the preceding June and his friends all noted that "Mr. G." had become strangely loath to take exercise and very inert in his movements. Indeed, he had detained the house-party in the house during lovely days while he orated to them on the folly of unnecessary exertion. It is an instance of how little we see ourselves as others see us that this supremely able man lived for years with a hydrocele that reached below his knees while he wore the tight breeches of the eighteenth century and was in the fond delusion that nobody else knew anything about it.

After leaving Sheffield House the hydrocele suddenly increased, as Gibbon himself says, "most stupendously;" and it began to dawn upon him that it "ought to be diminished." So he called upon Dr. Walter Farquhar; and Dr. Farquhar was very serious and called in Dr. Cline, "a surgeon of the first eminence," both of whom "viewed it and palped it" and pronounced it a hydrocele. Mr. Gibbon, with his usual good sense and calm mind, prepared to face the necessary "operation" and a future prospect of wearing a truss which Dr. Cline intended to order for him. In the meantime he was to crawl about with some labour and "much indecency," and he prayed Lord Sheffield to "varnish the business with the ladies," as if anything could any longer conceal the existence of this monstrous chimera.

He was tapped for the hydrocele; four quarts of fluid were removed, the swelling was diminished to nearly half its size, and the remaining part was a "soft irregular mass." Evidently there was more there than a simple hydrocele, and straightway it began to refill so rapidly that they had to agree to re-tap it in a fortnight.

The fortnight passed, and the second tapping took place, "much longer, more searching, and more painful" than before, though only three quarts of fluid were removed. . . . A few days later he was in great pain and moved with difficulty, the swelling again increased enormously, inflammation set in, and he became fevered.

Cline again tapped him and got away six quarts. Two days later he felt fairly well except for an occasional pain in his stomach, and he told some of his friends that he thought he might probably live for twenty years. That night he had great pain, and got his valet to apply hot napkins to his abdomen; he felt that he wished to vomit. At four in the morning his pain became much easier, and at eight he was able to rise unaided; but by nine he was glad to get back into bed. By eleven he was speechless and obviously dying, and by 1 p.m. he was dead.*

---

Editor's Note: Probably the tranquilizing euphoria of impending death. Poor fellow probably had a hydrocele and incarcerated hernia which became strangulated with the usual sequela of unattended strangulation.

Massive Diffuse Hypergammaglobulinemia

Its Diagnostic Significance

PAUL E. HERMANS, M.D.*
Rochester, Minnesota

THE PURPOSE of this report is to delineate pathologic conditions in which a considerable degree of hypergammaglobulinemia may exist.

Quantitative determination of serum protein fractions by paper electrophoresis is rather frequently carried out with the hope of obtaining a clue of diagnostic importance. But unfortunately in the majority of cases knowledge of the quantitative distribution of the serum protein fractions adds little to the process of diagnosis. Electrophoresis of serum proteins is a convenient method to demonstrate the presence of various hypogammaglobulinemic conditions. Hypogammaglobulinemia is now known to be an abnormality which is common to a number of immunologic deficiency syndromes, and which requires further study of the patient.[1]

There are a few additional electrophoretic patterns of particular significance, such as the characteristic homogeneous narrow protein peaks representative of the paraproteins which may be associated with multiple myeloma, Waldenström's macroglobulinemia, and benign monoclonal gammopathies.† Nephrotic syndromes also are frequently associated with a characteristic pattern of the serum protein electrophorogram.

In most illnesses, however, the changes of the serum protein fractions are "nonspecific", i.e., the electrophoretic patterns combine one or more of three changes: decreased concentration of albumin, increased amounts of α_2-globulins, and abnormally high concentrations of γ-globulins.

Several comprehensive studies of the various serum protein alterations which occur in many pathologic conditions are available, and the interested reader is referred to them.[2-4]

Material and Methods

Among 2,000 serum protein electrophoretic patterns taken at random, 112 patterns were found which had γ-globulin concentrations of 1.6 or more gm/100 ml serum. This pilot study naturally suggested that massive hypergamma-

---

*Mayo Clinic and Mayo Foundation: Section of Medicine.
†See Test Your Word Score Page 1637.

globulinemia was associated with only a limited number of clinical entities.

Several more thousands of electrophoretic patterns were then reviewed, and 40 instances in which the γ-globulin fraction measured 3 or more gm/100 ml were selected. The clinical diagnoses were obtained subsequently from the records of these 40 patients. The method of electrophoresis used at the Mayo Clinic for measurement of serum protein fractions has been described before.[5]

Findings

The diagnostic categories which were found in association with γ-globulin concentrations of 3 or more gm/100 ml of serum are listed in the Table.

Comments

The finding of massive hypergammaglobulinemia is of clinical importance to the practicing physician, for this protein abnormality considerably limits the number of diagnostic possibilities.

Usually multiple myeloma and Waldenström's macroglobulinemia are readily recognized by the narrow tall peak in the electrophoretic pattern, though further diagnostic procedures are required to differentiate the two conditions from each other.

After elimination of these plasma-cell dyscrasias by their recognizable paraprotein peak, there remain a limited number of conditions in which the pattern of the augmented γ-globulin has a broad diffuse shape. Conditions with massive diffuse hypergammaglobulinemia (3 or more gm/100 ml) include: (1) collagen diseases such as disseminated lupus erythematosus, scleroderma, Sjögren's disease, and rheumatoid arthritis (especially when taking the clinical form of Felty's syndrome); (2) sarcoidosis; (3) purpura hyperglobulinemica; (4) malignant lymphoma; (5) hepatic cirrhosis of the postnecrotic type, the type associated with chronic ulcerative colitis, and the type associated with porphyria cutanea tarda.

It is noteworthy that in this series no instance of a chronic infectious disease was encountered. This has practical significance, since fevers of undetermined etiology are particularly challenging to the diagnostician;[6,7] and the detection of massive diffuse hypergammaglobulinemia has been of help in the evaluation of some patients with fever of undetermined etiology. The finding of massive diffuse hypergammaglobulinemia in patients with perplexing fever warrants a further concerted effort toward the diagnosis of an underlying collagen disease or an occult lymphoma rather than an infectious process.

Of course, many patients having diseases of the above diagnostic categories never develop the degree of hypergammaglobulinemia review-

TABLE

Clinical Conditions Associated With Massive Hypergammaglobulinemia (3 or more gm/100 ml serum)

Clinical entities	γ-Globulin, gm/100 ml serum					Total Cases
	>7	6-7	5-6	4-5	3-4	
Multiple myeloma	3	1	3	7	1	15

Sjögren's syndrome	1				1	2
Scleroderma					2	2
Rheumatoid arthritis (Felty's syndrome)					2	2
Sarcoidosis					1	1
Purpura hyperglobulinemic					2	2
Lymphocytic lymphoma					2	2
Liver cirrhosis						
Postnecrotic				2	4	6
Chronic ulcerative colitis					1	1
Porphyria cutanea tarda					1	1
						40

*Lupoid hepatitis.

ed in this study.

Lymphogranuloma venereum, kala-azar, and visceral larva migrans are also rare conditions in which the serum γ-globulin concentration may be strikingly elevated;[8] but they were not encountered in the present series.

It should be emphasized that thousands of electrophoretic patterns were reviewed to obtain the 40 cases which were further analyzed, which indicates that massive hypergammaglobulinemia is a rare finding. On the other hand, when present it is of definite diagnostic help.

Robert W. Schulz, M.D.

The cover slide was taken in the fall of 1967 on the beach of Dr. Schulz's summer home property. It is a view of the lagoon on Madeline Island looking toward the recently developed Big Bay State Park.

It was taken with an Exakta VX1000 on Kodachrome II and early in the morning for lighting effects. Doctor Schulz graduated from the University of Minnesota Medical School and interned at St. Luke's Hospital in Duluth. He is in solo general practice in his fourteenth year in Fairmont.

In addition to photography, Dr. and Mrs. Schulz raise and show Irish setters and presently are raising and showing American saddlebred horses.

School of Salernum

She that hath hap a husband bad to bury,
And is therefore in heart not sad, but merry,
Yet if in shew good manners shee will keepe,
Onyons and Mustard-seed will make her weepe.

Regimen Sanitatis Salerni

Editor's Note: Speaking of onions and mustard seed: the School suggests that if a woman has to bury a husband she doesn't really love and is glad to get rid of, she can use onions and mustard seed to make her tears flow copiously—for the sake of appearance. How about that for resourcefulness?

Viscerospinal Syndrome

This syndrome consists of visceral disturbances resulting from irritation of the spinal roots and sympathetic nerves at various levels. Ussher in 1933 first described this concept of visceromotor and sensory changes in relation to deranged spinal structures as a visceral counterpart to Dejerine's radicular syndrome.

As described by Ussher there are three components to the syndrome: (1) cutaneous, muscular, or articular foci of spinal irritability; (2) peripheral sensory and motor mechanisms, the former including cutaneous hyperesthesia and intercostal neuritis, and the latter including muscle spasm or atony and vasomotor changes; and (3) viscerosensory component with pain, often the result of motor activity, and a visceromotor component including bronchospasm, ureteral stricture, pylorospasm, and hyperperistalsis. The viscera involved depend upon the level of the spinal cord affected.

Fatigue or acute increase in muscle tone are factors in aggravating peripheral symptoms. Correction of physiologic derangement or mechanical abnormalities, such as scoliosis of the spine or an articular facet defect, are reported by Ussher to yield surprisingly good results in many instances.

Centenarians

Of recent years physiologists have bestowed much attention on centenarianism, but only to find how elusive the problem is. Race does not solve it, nor climate, nor heredity, nor even careful living. Centenarianism is to be met with everywhere, and under the most diverse conditions. A scientific investigation of authentic cases, however, has proved that plain living, fresh air, recreation, and abstinence from strong drink and tobacco are important causes of the extreme prolongation of human life.

Adam, when he pleaded with Orlando to be allowed to become his servant and feared rejection on the ground of age, had the root of the matter in him.

> Though I look old, yet I am strong and lusty;
> For in my youth I never did apply
> Hot and rebellious liquors in my blood,
> Nor did not with unbashful forehead woo
> The means of weakness and debility;
> Therefore my age is as a lusty winter,
> Frosty, but kindly.

But if we do not know all the factors that make for an abnormally long life, and find it impossible to fix the relative values of those that are ascertainable, it is at all events open to us to study the lives of centenarians that have been publicly recorded, in order to discover what manner of men they were, how they lived, and worked, and passed the allotted span without the eye becoming dim or the natural force abated. By following their precepts, and taking stock of their habits, we, too, perchance, may live to the proverbial green old age, conditionally, of course, that we start the race of life with a sound constitution, and run it under circumstances similar to theirs—two not unimportant qualifications.*

Hematologic Toxicity of Chloramphenicol.

JOHN N. MORK, M.D.*
WAYNE H. THALHUBER, M.D.*
WILLIAM R. SWAIM, M.D.*
Minneapolis, Minnesota

An almost uniformly fatal aplastic anemia and the subsequent development of leukemia in patients treated with chloramphenicol emphasize the necessity for a careful, conservative approach when this drug is prescribed.

Two case reports will serve to highlight the pathogenesis, magnitude, clinical features and therapy presented by the infrequent patient who reacts so unfavorably to this antibiotic.

The introduction of chloramphenicol in 1947 was quickly followed by extensive use because of its high degree of efficacy with a wide range of infections and its apparent lack of toxicity. Originally obtained from a Streptomyces fermentation process, it was later synthesized and its chemical structure defined (Figure). The presence of the nitrobenzene ring and its potential toxicity was noted by Dr. J. E. Smadel.[1] However, in his large experience with the early use of chloramphenicol no toxicity was observed. The earliest report of hematological toxicity was by Volini et al. in 1950.[2] Fatal cases were first reported by Rich et al. in 1950[3] and, in 1952, by Loyd's report of fatalities.[4] Following the report of 24 cases of aplastic anemia associated with chloramphenicol administration,[5-10] 21 of which were fatal, the Food and Drug Administration[11] reviewed the drug, and a warning of hematologic toxicity was required of the manufacturer. Reports of toxicity then declined sharply. The decline was brief, however, and 83 fatal cases were reported in 1959 alone.[12] Since that date the American Medical Association registry on adverse drug reactions has reported a steady decline in the annual number.[27]

Case Reports

Case 1

A 45-year-old Caucasian female was admitted to Minneapolis Veterans Administration Hospital on 1/16/66 for intractable vaginal bleeding since 1/7/66. The patient had been treated by her private physician during the summer and fall of 1965 for an otitis media with penicillin and then, following cultures, with chloramphenicol. She took approximately 250 mgm. of the drug every four hours for six days in July. A three-day course of 250 mgm. every four hours was given 9/22/65 and repeated on 10/2/65. The patient related that she may have had the prescription refilled after this. Thus the total dose was in the range of 12-15 grams of chloramphenicol.

---

*Department of Medicine, Minneapolis Veterans Administration Hospital, Minneapolis, Minnesota.

The patient had a normal menstrual period on 12/20/65, but on 1/7/66 excessive vaginal bleeding appeared and continued. On 1/11/66 she was hospitalized by her physician. A hemoglobin was 10.2 gm%, the white blood count 1200/cu.mm., with 86% lymphocytes and 12% neutrophiles. A bone marrow aspiration showed depression of all developing cellular elements. Over the next five days she received twelve units of whole blood, antibiotics, vitamins K and B_{12}, liver, folic acid and estrogens. On 1/16/66 she was transferred to the Minneapolis Veterans Administration Hospital because of difficulty in obtaining blood and platelets at the outside hospital.

Physical Examination

The blood pressure was 80/65, pulse 125 per minute, temperature 101° F. The patient was a well developed, slightly obese middle-aged white female who appeared pale and weak. There were multiple ecchymoses, particularly prominent in the right upper arm and right breast. The liver and spleen were not palpable. There was no lymphadenopathy. The vagina contained approximately 300 cc. of blood and clots, and active bleeding was observed from the cervical os. The uterus was twice normal size, quite firm and irregular.

Course

The patient was given multiple transfusions during her first hospital days to replace the blood loss and to return the blood pressure to normal levels. She was septic and remained so throughout her hospital course. Urine culture grew out E. coli and gamma streptococci. A blood culture on 1/21/66 produced a pseudomonas species and on 1/24/66, E. coli. The initial hemoglobin was 7.0 gm%, the white blood count 1500/cu.mm. with 24% neutrophiles, 72% lymphocytes, and the platelet count 25,000/cu.mm. The patient received a total of 41 units of blood and several courses of antibiotics. She also received prednisone, B_{12}, folic acid, nicotinic acid, multivitamins, thiamine and a course of phenylalanine. The white blood count fell to 240/cu.mm. on 1/29/66. Later that day, severe hemoptysis, combined with vaginal bleeding, respiratory distress and shock, led to death.

Autopsy examination showed a hypocellular bone marrow, pulmonary and bowel hemorrhage, gram-negative rods in the lungs and liver, and a postmortem blood culture grew out E. coli.

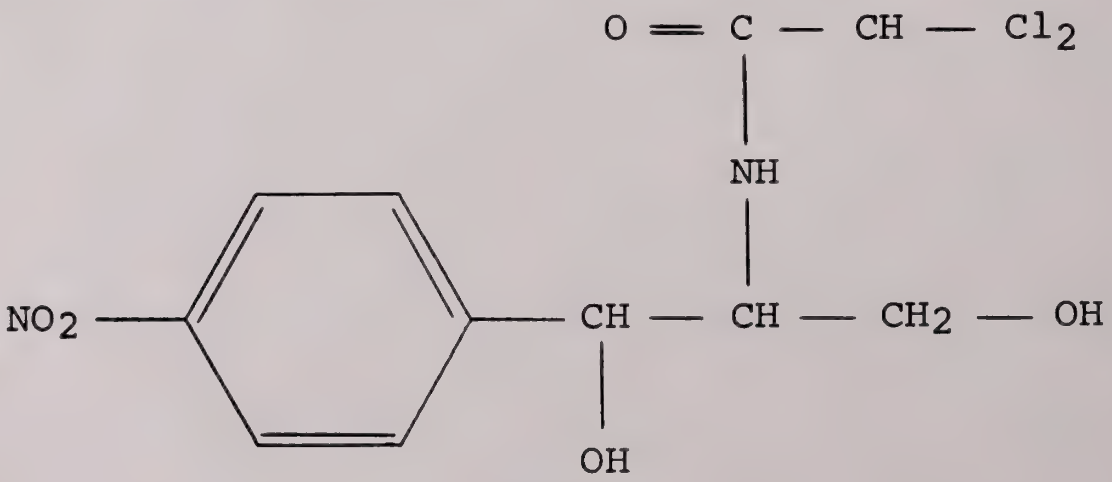
Case 2

A 65-year-old white male entered Minneapolis Veterans Hospital on 6/3/58 with symptoms and signs of intestinal obstruction. An operation had been performed at another hospital for lysis of adhesions and decompression of intestine obstruction five weeks prior to admission. On 6/18/58 a left hemicolectomy was performed and adenocarcinoma was found in the sigmoid colon. The regional nodes were not involved with tumor. Postoperatively the patient developed a pneumonia which was treated with penicillin 1,200,000 units and streptomycin 1.0 gm. b.i.d. from 6/20 to 6/27. On 6/27/58 chloromycetin 250 mg. q.i.d. was started and increased to 1.0 gm. q.i.d. on 6/30 through 7/9/58. The changes in white count, hemoglobin and platelet count are outlined in the Table.

The patient subsequently recovered from the surgery and postoperative pneumonia and was discharged. He returned to the Sioux Falls Veterans Hospital in 1960 with acute congestive heart failure. The hemoglobin was 13.5 gm% and the white blood count was 8750/cu.mm. with 80% neutrophiles and 12% lymphocytes. He was found to have metastatic adenocarcinoma and expired after a three-and-a-half month hospitalization. Autopsy examination showed a pale, fatty bone marrow which was not examined microscopically.

Clinical Picture

In patients developing aplastic anemia, as in Case 1, the onset is usually insidious with



Figure

gradually developing weakness and fatigue. Purpura or spontaneous bleeding from the nose, gastrointestinal or genitourinary tract may be the initial manifestation but most often comes after the onset of weakness and fatigue. Infections, while frequently the cause of death, are rarely the presenting manifestation.

Physical Findings

Physical examination usually shows a patient with a waxy pallor, often with ecchymoses, petechiae or spontaneous hemorrhage (epistaxis, rectal bleeding or menorrhagia). Late in the disease, ulcerations in the mouth or pharynx may appear, occasionally with a low-grade cellulitis in the neck. Splenomegaly is rarely present and when present is not of great magnitude. A markedly enlarged spleen is cause to doubt the diagnosis of drug-induced anemia and to suspect another cause, e.g., an "aleukemic" leukemia.[12]

Bone Marrow

Lesser damage to the marrow results in a wide spectrum of historical and physical findings. Case 2 showed an acute onset and apparently complete remission. A patient may have no clinical findings, the marrow damage being suspected only with examination of the peripheral blood for an unrelated condition. Historical and physical manifestations of similar nature, but less severe than those described for aplastic anemia, are observed in patients with milder forms of marrow damage.

Yunis and Bloomberg have divided chloramphenicol toxicity into two distinct types[13]: (1) a dose-dependent reversible type which appears concurrently with drug administration, and (2) the aplastic anemia variety which is not clearly dose-related and is usually fatal. It is implied that the reversible type represents the pharmacologic effects of chloramphenicol. Other distinguishing features include the following[13]:

TYPE I

Dose-dependent-reversible
Comes on during drug administration
Causes the erythropoietic lesion—no aplasia
Represents the pharmacologic effect
Median duration of therapy—20 days

TYPE II

Aplastic anemia—fatal
Delayed onset
No erythropoietic lesion seen
Represents idiosyncratic effect
Median duration of therapy—35 days

Bithell and Wintrobe[27] and Best[17] find that chloramphenicol toxicity is better described as a continuum of adverse effects. In Best's series of 408 cases reviewed from the AMA drug registry, there was significant overlap between Types I and II. Nine of 60 patients with

TABLE
Clinical Course of Patient 2

Date	WBC (leukocytes/cu. mm.)	Hgb. (grams/100 cc.)	Platelet Count (platelets/cc. mm.)
6/22	6,000	—	196,000
6/24	5,800	—	108,000
6/26	5,550	—	130,000
6/27			Chloramphenicol 1 gm/day
6/28	2,800	—	147,000
6/30	2,200	—	75,000 Chloramphenicol 4 gm/day
7/2	1,555	12.1	49,000
7/4	1,850	12.1	19,000
7/6	2,200	14.6	44,000
7/8	2,200	13.6	20,000
7/9	1,500	12.9	17,000 Chloramphenicol discontinued
7/12	1,550	14.0	21,000
7/14	1,700	13.8	18,000
7/15	3,850	14.0	23,000
7/17	5,500	14.6	42,000
7/21	9,050	14.4	205,000

Whole blood transfusions were given on July 1, 2, 3, 4, 10 and 14.

normocellular marrows had a two-week delay between the last dose of chloramphenicol and the appearance of toxicity. These data strongly suggest a continuum of marrow damage, and this view is supported by Bithell and Wintrobe.[27]

Metabolism

Chloramphenicol is completely absorbed from the gastrointestinal tract and reaches a serum concentration of 20-40 μg/ml. after a one-gram oral dose.[13] It is concentrated in the liver, lungs and kidneys. Detoxification occurs in the liver with formation of a glucuronide, 85% of a given dose being excreted in the urine within 24 hours. Only 10% of the excreted chloramphenicol is in an active form.[13] Thus, in uremic patients, the half-life of the metabolic products is increased, while patients with hepatic insufficiency have an increased half-life of the active form.[14] The bone marrow concentration parallels the plasma concentration. There is no evidence of sequestration of chloramphenicol in the bone marrow.[13]

Magnitude of the Problem

In assessing the magnitude of the problem with chloramphenicol toxicity, there are several avenues of approach. Complicating this assessment are inadequate reporting of toxic effects and frequent multiple drug ingestion in patients presenting with evidence of marrow injury.

Total Drug Distribution

The following figures from Parke-Davis Company* give the total number of grams of chloramphenicol distributed yearly from 1962 through 1967.

1962	26,427,000 gm.
1963	29,001,300 gm.
1964	28,382,900 gm.
1965	31,310,600 gm.
1966	32,834,500 gm.
1967	31,859,800 gm.

These figures reflect a yearly increase in distribution up to 1967, when Parke-Davis' patent rights expired and the drug was distributed by other companies. Inadequate reporting of toxic effects precludes precise correlation of toxic effects with total drug distribution.

Number of Adverse Reactions

The total number of chloramphenicol-associated blood dyscrasias reported to the AMA Registry on Blood Dyscrasias between 1953 and 1964 was 408, as reported by Best.[17] Forty cases formed the basis of an incomplete review of British experience.[18] Other reports include Yunis and Bloomberg's reported 94 cases of chloramphenicol-associated blood dyscrasias,[13] 21 of which were also included in Best's series.

Mortality-Morbidity

The Committee on Safety of Drugs of the British Medical Association reported 24 fatal cases of blood dyscrasias following chloramphenicol administration during 1965-66.[23] This comprised 80% of the reported fatalities from aplastic anemia during that time period. Unfortunately, not all of the patients listed in these reports were given the drug on the basis of the strict indications[17] called for in 1952[11] and repeatedly since that time.

Incidence

As stated above, the incidence of unfavorable hematological reactions to chloramphenicol is difficult to determine, as estimates vary widely. In 1952 Wilson[5] reported on 62 patients who had prolonged chloramphenicol administrations, one gram twice weekly, for bronchiectasis. Two developed aplastic anemia and one died: an incidence of one in 31 courses. Smick[24] derived an incidence of one in 60,000 four-gram "courses" of chloramphenicol. This was thought to be an underestimate of the rate of occurrence because of under-reporting of the toxic reactions. With the highly variable frequency of detecting and reporting adverse effects following chloramphenicol, it is difficult to properly assess the magnitude of the problem. Chloramphenicol remains the leading cause of drug-induced aplastic anemia in this country and Great Britain.[17,24-26] In addition, chloramphenicol has recently been implicated in the causation of leukemia.[19-21]

---

*Kindly supplied by Dr. J E. Gajewski, Parke-Davis Co., Detroit.

Pathogenesis

The pathogenesis of chloramphenicol toxicity is not well understood at this time. Theories invoking the pharmacologic effect of the drug, auto-immunity and genetic susceptibility have all been proposed, but none proven.

Several features relevant to the pathogenesis have been observed. Chloramphenicol inhibits protein synthesis in rapidly proliferating tissues. Inhibition of protein synthesis was found to occur on the basis of inactivation of template ribonucleic acid.[28] Abnormal vacuoles in the proerythroblasts of the marrow can uniformly be induced by the administration of large doses of chloramphenicol.[31-34] Iron turnover is routinely inhibited by administration of large doses of chloramphenicol and precedes any morphologic evidence of marrow injury.[13,27,29,30] Scott et al. provide evidence that the abnormal iron metabolism is dose-related, with 6 gm/day routinely producing a decreased utilization of iron.[15] Bithell and Wintrobe suggest that the stem cell is the major site of injury, regardless of the mechanism of that injury.[27] Chromosomal breakage and vacuolization were observed following high doses of chloramphenicol.[39] Chromosomal injury could thus be the unifying mechanism for all the hematologic toxicity of chloramphenicol.

Long-Range Sequelae

It is the rare patient who survives chloramphenicol-induced aplastic anemia. Continued marrow hypoplasia with subsequent leukemia is illustrated in a case reported by Cohen and Creger.[19] Their patient was a young woman whose chloramphenicol-induced aplastic anemia was diagnosed in 1958 and who needed frequent blood transfusions until androgens were effective in raising the hemoglobin to acceptable levels. Seven years after the onset of marrow aplasia, the patient became resistant to androgens, developed acute myelogenous leukemia and died.

In a followup study, Fraumeni[20] reports a total of eight cases of leukemia following chloramphenicol-induced aplastic anemia. He reviewed the literature and found 13 cases of leukemia associated with prior chloramphenicol, two of them with aplastic anemia. In the eight patients who developed leukemia, three followed a sequence of drug—marrow aplasia with no evidence of leukemia—i.e., leukemia at least 18 months after the drug. This corresponds well to the sequence of events observed in irradiation-induced leukemias.

Additional cases of leukemia following chloramphenicol-induced marrow aplasia were described by Brauer and Dameshek.[21] Their three patients, like four of five of Fraumeni's, were all females over 35 who developed acute myelogenous leukemia. The time intervals to onset of leukemia were eight years, 14 months, and 18 months after the onset of marrow hypoplasia.

Acute myelogenous leukemia and chronic myelogenous leukemia are also seen following benzene or irradiation-induced marrow aplasia.

Since chloramphenicol-induced aplastic anemia is rare and usually fatal, it is not surprising that the late complications are just now being described. The fact that similar development of leukemia has followed other "induced" marrow aplasia, i.e., benzene, phenylbutazone and irradiation, should give added significance to the several reports of leukemia that have followed chloramphenicol-induced aplasia.

Treatment of Chloramphenicol Toxicity

Transfusions

Erythrocyte and leukocyte transfusions, platelet packs, antibiotics, isolation, androgens, and corticosteroids are useful in bone marrow aplasia but have largely failed to lower the overall mortality.

Phenylalanine

In 1965, Ingall and coworkers reported that phenylalanine reversed the bone marrow vacuole formation induced by chloramphenicol.[16]

Ward, however, was unable to reverse the *in-vitro* inhibition of hemoglobin synthesis by chloramphenicol with large quantities of phenylalanine.[35] Greenberg reported two adult patients in whom he was unable to reverse the chloramphenicol-induced abnormal ferrokinetics with phenylalanine.[36] Patient #1 also failed to respond to large doses of phenylalanine. It has been shown that phenylalanine *in vitro* does not effect suppression of phytohemagglutinin mitosis induced by chloramphenicol.[37] So it is doubtful that phenylalanine is the answer to chloramphenicol toxicity.

Bone Marrow Transplants

An attempt to treat hypoplastic anemias with marrow transplantation in a controlled study showed no significant improvement in survival for the twenty patients treated. In four of the twenty cases, marrow hypoplasia was attributed to chloramphenicol administration. One of the four showed a favorable response to marrow transplantation,[22] but this could not be substantiated subsequently.[12]

Cessation of Therapy

Monitoring the serum iron, iron-binding capacity and reticulocyte count is a means of detecting erythroid suppression in those patients receiving the antibiotic.[14,27] Even careful monitoring, however, is no guarantee of avoiding irreversible[13] marrow damage; therefore some authors[27,17] find it difficult to continue chloramphenicol in the face of manifest bone marrow injury and advocate cessation of therapy at the earliest sign of toxicity.

A dose of two grams of chloramphenicol per day has been proposed as a means of decreasing the incidence of dyscrasias.[15] However, the development of aplastic anemia has not been shown to be dose-dependent, so that aplasia cannot with certainty be avoided with any dose schedule.[27]

Hepatic and renal insufficiency which modify the conjugation and excretion of chloramphenicol should be considered as relative contraindications to its use.[14,27] The frequency of marrow aplasia is increased with intermittent therapy; therefore intermittent administration of the drug is to be avoided.[13,17,27]

Prognosis

The following factors have been found to favorably influence prognosis[13,17]:

1. Fewer cell types depressed in both the peripheral blood and in the bone marrow;
2. A shorter delay in onset of marrow toxicity;
3. A larger daily dose of chloramphenicol (rapid induction of marrow suppression is more often reversible);
4. Occurrence in persons of the negro race;
5. Fetal hemoglobin above 400 mg%.

The mortality rate is quite high for the delayed-onset, hypoplastic group. In Yunis and Bloomberg's group of 94, 43 patients showed delayed onset, and 38 of these died.[13] In this same series, 49 patients had the onset of marrow suppression during chloramphenicol, and 11 of these died (Figure 3).

Figures from the AMA registry show that 108 of 279 patients with chloramphenicol-associated marrow toxicity had died, 96 had recovered, and 75 were alive with sequelae.[17] There were 31 deaths among 40 cases reported by Sharp.[18]

Bloom and Diamond[38] report 11 children with chloramphenicol-induced marrow aplasia, nine of whom died. Eight of eight with a fetal hemoglobin value below 400 mg% died, whereas only one of three with a value above 400 mg% died.

Prevention

The most effective means of avoiding toxicity from chloramphenicol lies in prevention. Most of the 408 patients in Best's review received chloramphenicol in the recommended dose and duration. However, it was alarming to note the fatal cases of aplasia which resulted from treatment of the common cold, acne, and viral and bacterial respiratory infections with chloramphenicol. A decrease in the unwarranted use of chloramphenicol is the chief means of prevention now available to physicians.[13,17,27]

Summary

Two diverse cases serve to emphasize the variability of the hematologic complications of chloramphenicol toxicity. Difficulties in assessing the magnitude of the problem are largely related to lack of complete reporting of cases. A review of pathogenetic factors fails to completely explain the genesis of chloramphenicol-associated marrow injury. Leukemia has recently been reported as a late complication. Treatment of the aplastic anemia is quite unsatisfactory. Another case (Case 1) unresponsive to phenylalanine is reported. The prognosis for a patient with both pancytopenia and hypocellular marrow is almost nil. Factors influencing prognosis are reviewed. A decreased use of chloramphenicol remains the chief means of preventing its dangerous hematologic toxicity.

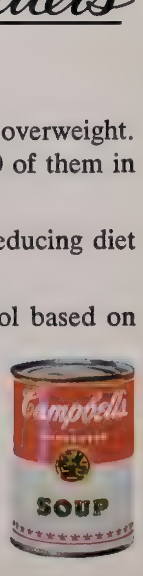
Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N.J. 08101



Pro-Banthīne® Helps...

propantheline bromide

...REVEAL the ulcer
...HEAL the ulcer

The efficiency of Pro-Banthīne—its favorable balance of therapeutic and secondary actions—has been thoroughly tested and observed. This quality has been demonstrated surgically, roentgenographically, cinegastroscopically and, above all, clinically.

When physicians needed to relax the restless duodenum for the recently refined technic of hypotonic duodenography they logically turned to Pro-Banthīne.

For years Pro-Banthīne has been the most widely used anticholinergic medication for calming the gastrointestinal tract—for suppressing secretion, prolonging the action of antacids and providing the proper environment for healing peptic ulcers.

These established therapeutic actions make Pro-Banthīne particularly useful in:

- peptic ulcer
- gastritis
- diverticulitis
- irritable colon
- biliary dyskinesia
- functional hypermotility

We wish to thank Drs. Marcia K. Bilbao, Louis H Frische, Josef Rösch and Charles T. Dotter for this exceptionally graphic example of hypotonic duodenography

---

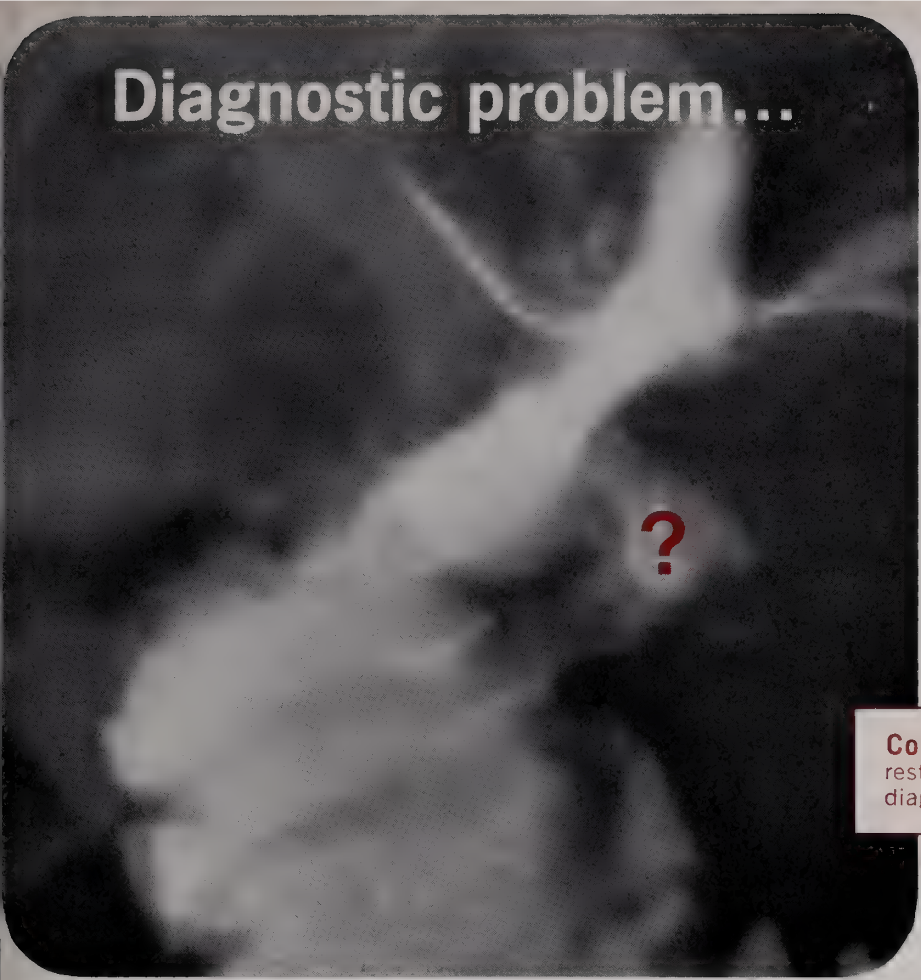
Contraindications: Glaucoma, severe cardiac disease.

Precautions: Since varying degrees of urinary hesitancy may occur in elderly men with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

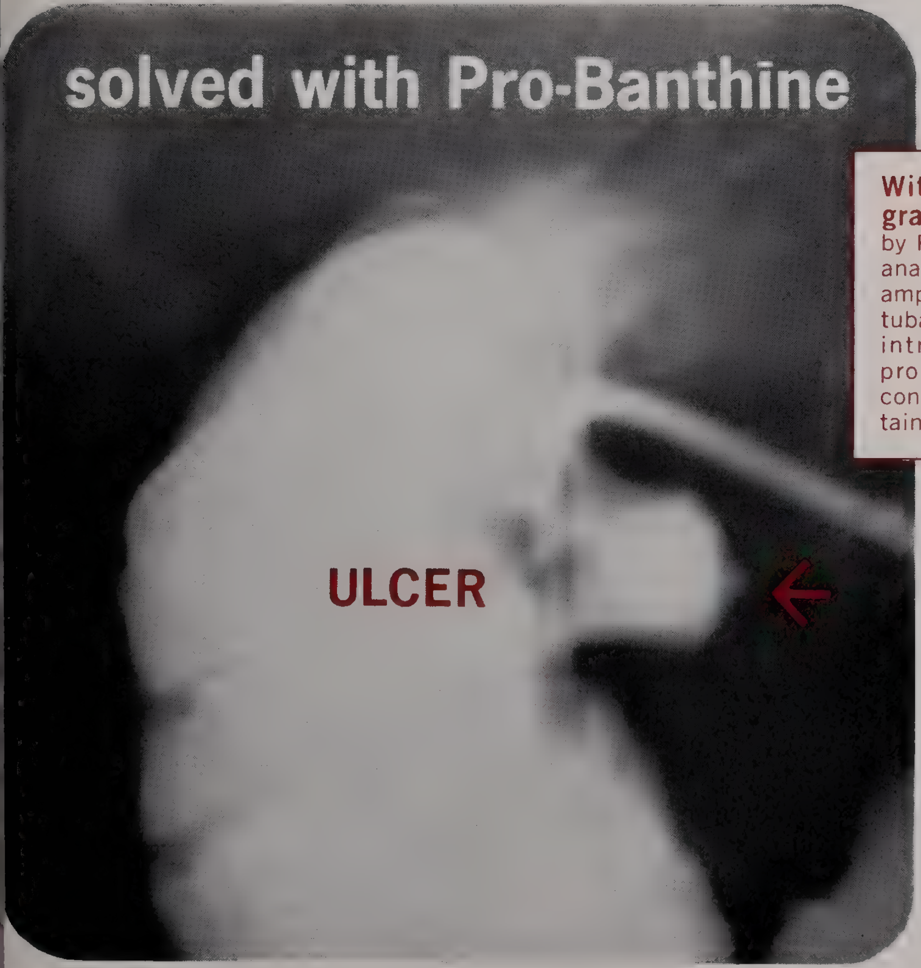
Dosage: The maximal dosage tolerated without excessive side effects is usually the mos effective. For most adult patients this will b four to six 15-mg. tablets daily in divide doses. In severe conditions as many as tw 15-mg. tablets four to six times daily may b required. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets o 15 mg., as prolonged-acting tablets of 3 mg. and, for parenteral use, as serum-typ vials of 30 mg. The parenteral dose shoul be adjusted to the patient's requirement an may be up to 30 mg. or more every six hours intramuscularly or intravenously.

SEARLE *Research in the Service of Medicine*



Diagnostic problem...
?

Conventional x-rays of the restless duodenum are often diagnostically indefinite.



solved with Pro-Banthīne
ULCER

With hypotonic duodenography duodenal calm induced by Pro-Banthīne permits clear anatomic appraisal. In this example the duodenum was intubated. Pro-Banthīne, 60 mg. intramuscularly, produced prompt aperistalsis. Double contrast visualization was obtained with barium and air.

What's Polycillin® (ampicillin trihydrate) got to do with the price of bananas?

Just this: According to the U.S. Bureau of Labor Statistics, bananas are one of the few things that actually cost less today than five years ago. The same is true of Polycillin. In fact, the price of Polycillin has been reduced about 30% since its introduction in 1963...making it, according to national surveys of patient costs, as economical as leading brands of tetracycline and erythromycin. And Polycillin is available in a variety of dosage forms for your patients—more than any other ampicillin. It comes in 250 mg. and 500 mg. capsules; in convenient, chewable tablets of 125 mg; oral suspension, 125 mg. and 250 mg. per 5 ml.; and in pediatric drops, 100 mg. per ml. Also available parenterally as Polycillin-N (sodium ampicillin).

Malignant Tumors in Children

DURING THE PAST thirty years, the prevention and treatment of many bacterial and viral diseases have diminished their role as a cause of death in children. Similar improvements have not been as striking in the cure of malignancy; therefore the importance of neoplasms has become relatively greater. Malignant tumors now rank second only to accidents as a cause of death in the age group from one to fifteen years.

In this issue,* Doctors Mahour and Lynn present a very interesting review of the remarkable variety of tumors encountered during the pediatric span. The importance of teamwork on the part of the clinician, radiologist, surgeon and pathologist is stressed in the diagnosis of neoplasms. Each physician involved in the care of children should maintain a high index of suspicion regarding tumors and in seeking the cause of symptoms not readily explained.

Progress in pediatric oncology† has been hampered by many factors, including the obvious difficulty in conducting controlled series to evaluate different methods of treatment. In addition, the sporadic distribution of affected patients slows the evaluation of new treatment techniques until a significant series accumulates. A most encouraging trend to combat these problems is the national and regional cooperation of physicians interested in childhood malignancy, combining their data in controlled studies and sharing the information derived.

Just as teamwork was stressed in the initial diagnosis of neoplasms, it is vitally important in the subsequent management of the patient. Close collaboration of the attending team, including the child's regular physician, will minimize delays, concentrate the available knowledge and avoid confusion for the family.

There is ample reward for the extra effort in the gratification of seeing a child cured and in the increased skill and knowledge acquired by the team. If the disease should progress toward a fatal outcome, we must remember that "incurable" does not mean "untreatable;" and the team must continue to assist in a genuine effort to sustain the comfort and morale of the young patient and his family.

100
Rx
THE COST OF AMBAR EXTENTABS IS APPROXIMATELY ONE HALF THAT OF OTHER LEADING APPETITE SUPPRESSANTS
AN IMPORTANT FACTOR IN LONG TERM THERAPY

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety... helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

Electronic Pacemakers

The development of implantable artificial electronic pacemakers as reviewed by Bonnabeau and Lillehei[1] has been one of the major medical advances of this century. Patients with complete heart block who ordinarily would have had a life expectancy of one year or less may now be returned to useful life, with the Damocles sword of Adam-Stokes attacks effectively removed.

The combination of implantable battery unit and bipolar intracardiac catheter has obviated the need for thoracotomy and made the procedure a benign one that can be performed under local anesthesia, even with patients of advanced age who are poor surgical risks. The development of a demand type pacemaker which can be inhibited if normal sinus rhythm returns has almost entirely eliminated the problem of pacemaker-induced arrhythmias.

A difficult problem is posed by the patient who has a history of syncopal episodes with slow pulse but who, at the time of admission to the hospital, is found to have normal sinus rhythm. The patient should be monitored and, if episodes of transient AV block are demonstrated, a demand pacemaker should be inserted. A helpful clue in this situation is the presence of right bundle branch block with marked left axis deviation. This suggests partial bilateral bundle branch block.[2]

Another development in the use of pacemakers has been the treatment of arrhythmias. Patients with recurrent ventricular tachycardia refractory to medical management have responded to pacemaker treatment with the rate of the artificial pacemaker set fast enough to inhibit the ectopic focus.[3]

After a decade of use the implantable electronic pacemaker is here to stay.

Post-Intubation Granuloma of the Larynx

Post-intubation granuloma, described in Minnesota Medicine,* although not a common complication of general endotracheal anesthesia, must be suspected in a patient with "choking" and hoarseness following intubation. The site of the lesion in the posterior or "breathing" area of the laryngeal introitus explains why breathlessness or choking may precede hoarseness.

Anesthesiologists, of course, are aware of this problem; but their meticulous fitting and placement of endotracheal tubes may be offset by enthusiastic passive head movements and other head positions required in certain surgical situations. Recognition of the etiologic factors by all operating-room personnel should be expected to keep this a relatively rare complication of endotracheal anesthesia.

"All Interns are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.

Corrective Surgery in Elderly Patients
A Dilemma

As surgical skills and supportive techniques become honed to a sharp edge of perfection, those patients whose tolerance for a major intervention or stress is marginal may often be offered corrective surgery—even open heart surgery. Age alone is not to be regarded as an absolute contraindication to a given operation; rather it merely enters into the balance of pros and cons that determine the advisability or inadvisability of a procedure. In the last analysis, this balance involves the odds for death or disability if operation is performed, as opposed to nonintervention. The octogenarians operated on by Kiser and associates,* as reported in this journal, had less to gain from operation because life expectancy at their age was shorter; thus the cost and pain of operation would be rewarded by a much diminished period of benefit resulting therefrom. Also, the risk and morbidity for patients in their seventies, everything else being equal, must surely be higher. But even these less favorable indications for operation may not be of sufficient importance to militate against the scalpel, because longevity and the pleasure of living may be so improbable otherwise that operation becomes an attractive alternative, as for these patients of Kiser, Peterson, and Johnson, and for several of our own patients.

It might be of interest, and indeed is now becoming something of a necessity, to pursue this line of reasoning to a more radical conclusion—or dilemma(?). Suppose that an aged patient has a life-threatening malfunction, for which a corrective or highly palliative and safe therapeutic intervention is available. According to the previous reasoning, this therapy, or even surgery, is justified and indicated. I have in mind, as an example, the development of heart block, with its attendant syncope, cardiac failure, or sudden death, and the availability of pacemakers placed transvenously and under local anesthesia at very low risk but considerable expense. But now suppose the patient, in addition to old age and heart block, has senility, loss of memory, painful arthritic contractures, personality derangement and paranoia, and failing vision. Neither the patient, his relatives, society, nor the doctor can muster enthusiasm for the insertion of a pacemaker to prolong his deteriorating existence. But exactly where is the line to be drawn? And when is that line crossed? Who is to assume the responsibility of decision?

These are the same unanswered questions that have made merciful euthanasia unacceptable. However, the advances of medical science prevent further deferment of this issue. Indeed, euthanasia by the withholding of supportive therapy is now generally considered acceptable for certain terminal patients with incurable disease, such as cancer. Senility also is incurable, and its ravages are extensive. Most physicians and surgeons already practice a modified form of euthanasia by withholding treatment from the most pitiful of the aged and infirm.

Hopefully, the perfection of artificial hearts and similar modalities will not precede the formulation of ethical guidelines for the physician to follow in his practice of modified euthanasia. But if pacemakers, artificial valves, and even artificial hearts can be withheld so as not to prolong a patient's incurable senility, why not the same for antibiotics, vitamins, or even nutriment. And if we are to manipulate the phenomenon of death by withholding these available means of prolonging life in order that death may arrive sooner through infection, inanition, or congestive heart failure, why should we tolerate even these extended and miserable types of death? Once senility has irreversibly destroyed the personality and disrupted meaningful contact with reality, should we not be consistent in our mercy and *invite* death's painless and welcome peace?

Vaginal Hysterectomy*

VAGINAL HYSTERECTOMY is one of the oldest gynecologic operations known. The excessive morbidity and mortality of operative procedures performed prior to this century, when coupled with the inherent complications of vaginal surgery itself, caused vaginal hysterectomy to fall into disrepute.

With the advent of improved anesthesia, transfusions, antibiotics, and postoperative care of medical complications, vaginal hysterectomy has rightfully gained a respectable role in the armamentarium of the pelvic surgeon. Mayo, Heaney, Counsellor, Pratt, and others have demonstrated that the procedure can be done with a low rate of mortality, diminished operative time, shortened hospitalization, and a minimum of significant complications. However, the improvements themselves are not indications for a major operative procedure when medical therapy, with no risk, may be as effective or when a minor procedure such as curettage may suffice.

In the present-day practice of gynecologic surgery, approximately half of the hysterectomies performed are carried out through the vagina. This proportion has been maintained during the past 10 to 15 years when appropriate indications are observed.

Several factors concerning the indications for vaginal hysterectomy should be stressed. The data from the large series of Tasche demonstrate once more that the two main indications for vaginal hysterectomy are abnormal vaginal bleeding and symptomatic pelvic relaxation. Other symptoms as well as findings on pelvic examination may give a summation effect, indicating vaginal hysterectomy, with or without repair, when no one symptom or finding in itself would be an indication for a major operative procedure.

Although vaginal bleeding is a common indication for hysterectomy, the possibility of malignancy *must* be ruled out prior to the performance of a definitive procedure that may not be the treatment of choice for a malignant condition. A negative smear does not rule out the presence of malignancy in the female pelvis and means only that malignant cells were not seen. If a cervical abnormality is noted, a biopsy specimen should be taken; if there is abnormal bleeding, a definitive diagnosis must be made by means of curettage; and if there is discharge or any other findings indicative of malignancy, the possibility of malignancy also must be ruled out prior to the performance of a simple vaginal hysterectomy.

In invasive carcinoma of the cervix, vaginal hysterectomy is inadequate when performed alone. The five-year survival rate for invasive carcinoma of the cervix treated by simple hysterectomy is 14%, as compared to the 85% anticipated with proper treatment. Similarly, in carcinoma of the endometrium, bilateral salpingo-oophorectomy probably should be done in addition to the hysterectomy, as a simple hysterectomy may not be adequate. In carcinoma of the endometrium, vaginal hysterectomy with bilateral salpingo-oophorectomy gives excellent results, comparable to those with the abdominal approach. However, the abdominal approach is preferable because it allows for more adequate exploration so that extension of the disease process may be treated properly; it also decreases the risk of adnexectomy.

Any organic disease that will cause persistent vaginal bleeding may be properly treated by means of vaginal hysterectomy. As a major operation, vaginal hysterectomy, in the absence of organic disease, should be carried out *only* when the bleeding is recurrent or has not responded to previous curettage or hormone therapy.

Symptomatic pelvic relaxation is now the primary indication for vaginal hysterectomy. Although vaginal hysterectomy is presently the treatment of choice, the operation is incomplete without repair of other damaged tissues, cystocele, urethrocele, rectocele, and enterocele. Symptoms of pelvic pressure, bearing down, falling out or bulging of tissue, and stress incontinence may be expected to be ameliorated by vaginal hysterectomy and repair. Urgency incontinence is often noted in conjunction with these symptoms; however, the urgency is related to irritation of the bladder and will not be ameliorated necessarily by any surgical pro-

cedure, whereas correction of the urethrovesical angle by means of plication and cystocele repair is designed to correct stress incontinence. Only if the urgency incontinence from the irritated bladder is secondary to its prolapse is the urgency incontinence likely to be improved by vaginal repair.

Just as vaginal repair is an integral part of the hysterectomy performed for symptomatic pelvic relaxation, the converse is equally true. Only in the most extenuating circumstances is vaginal repair indicated without performance of vaginal hysterectomy. Technically, the damaged tissues can be better repaired with the uterus removed. Subsequently, the uterus will not adversely affect the repaired region, either by pregnancy or tumor formation. Because the uterus is the site of about 12% of malignant lesions in the female, it should be removed at major pelvic surgery unless there is a decision to maintain the function of childbearing.

Inasmuch as the chance for success is best in the first operation performed for pelvic relaxation, the procedure must be done completely at the initial attempt. The single most important measure in preventing recurrence of prolapse is the obliteration of the cul-de-sac and repair of the enterocele, whether obvious or incipient. Careful attention to surgical technique during the operative procedure will decrease the morbidity. Previous pelvic surgery and pathologic conditions alert the surgeon to expect complications during vaginal hysterectomy. The procedure should be performed when it is considered to be the proper operation for the patient's condition and when it carries the least risk to the health and wellbeing of the patient herself. Tasche's article demonstrates again that an experienced surgeon may safely perform vaginal hysterectomy with a minimum of risk and morbidity to the patient. In addition to the surgical technique, the appropriate indications and contraindications must be observed to provide good results.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

The Editor's Soliloquy

Canned Consultation

THROUGH NORTHLAND REGIONAL the federal government has provided consultation for the doctor "in the far corner of the state" who lacks the availability of highly trained specialists in the adjoining office or down the street. All he has to do is lift the receiver and dial the number: 1-800-356-8103. A mechanical voice speaks out and gives him an official consultation.—Easy, wasn't it? The consultation didn't cost a dime; even the phone call was free.

The calling physician has no opportunity either to greet the disembodied voice with a cheery "Hi" or to conclude the non-stop interview with a warm "Thank you" or "Goodbye." He has no chance to establish professional rapport with another gentleman through the subtle reciprocity of voice inflections conveying understanding, assurance and confidence. There is no possibility of interrupting the steady flow of words with a polite query for clarification: "What was that again?" or to inject a responsive remark: "That sounds encouraging; I'm glad you mentioned that!" There is no intimately mutual and profitable exchange: just a continuous monologue over the wire, calculated to leave the frustrated caller feeling nullified.

Does it sound as if I'm being facetious? You're right, I am! But if, under my jocosity, you, the reader, fail to detect a deep concern, then you don't know your Editor. In this state of ours, where medicine is practiced on the highest grade, the federal government is spending one and a quarter million dollars to implement this and other innovations for the postulated "improvement" of the physician, with not one penny of this money allocated to the care of the "neglected patient."

Does this not seem like a shocking reversion of priorities: another of those confounding paradoxes the perversely meshed gears of our complex age have been producing so abundantly of late? It is!

Can you imagine any physician, any specialist, who would not willingly provide free telephone consultation at any time, day or night, to any colleague who needed and requested it? Why not call up Northland Regional and ask them to spend some of that one and a quarter million dollars to pay for the phone calls? We'll give the consultations free, and they won't be canned! Try it!

Carl O. Rice, M.D.

Old Doc Hess says: Expounding too contentiously about the infinite advantage of one minutia over another begins to assume the proportions of a cult—not a science. COR

The excesses of our youth are drafts upon our old age, payable with interest about thirty years after date.—Colton

(President's Letter continued from page 1583)

and the training-grant facilities have improved this opportunity.

The National Program for Dermatology recently formulated by the American Academy of Dermatology outlines programs for various types of professional and nonprofessional personnel, facilities for the care of diseases of the skin, types of required equipment, and specific projects designed to solve the major public and personal health problems related to the skin. The guide thus provided demonstrates and can help answer most of the needs of the American public in respect to dermatology. Three members of the 15-man National Council for Dermatology were trained in Minnesota.

In Minnesota we are in the happy position of being among the leaders both in providing care and in providing professional personnel in dermatology. The progress we have made and our position of leadership throughout the country must not dull our capacity for self-assessment, however. The University of Minnesota, for instance, does not have a full-time professor of dermatology. It is well accepted that three full-time faculty positions are the minimum necessary for the satisfactory conduct of a department. The level of financial support provided by the legislature for our state medical school is far below that given to most other state-supported schools in the United States. The University of Minnesota Medical School receives a third or less of its budget from the State of Minnesota. It is a tribute to the personnel of the University of Minnesota that they have maintained their excellent standard of medical care, teaching and research in the face of the deprivations and restrictions with which they must deal. The evolution of a second medical school in this state would carry with it the promise of full-time faculty positions so that new departments, and not only departments of dermatology, could develop from the beginning.

Emerging Patterns of Medical Care and Practice

The central plot of this story is, in a sense, the central plot of all social history —man's struggle to rearrange his social organization and institutions, to keep pace with his accumulating knowledge, changing needs and altered environment. As in all phases of human enterprise, realistic available choices are limited, but they are not absent. Freedom to avoid the basic fact of change does not exist—either biologically or socially—but the character and adequacy of the adjustment to change is, in varying limits, subject to human decision. It is, of course, possible for a society or a group to attempt to resist adjustments altogether—either actively or by inertia—but the price is to be run over.*

Man of Action

Musician Fats Waller says he became acquainted with a set of twin brothers. One was a minister and the other a doctor. He met the medical brother on the street one day and said, "I wish to compliment you on your fine sermon last Sunday, Doctor."

The twin shook his head and replied, "I'm sorry Waller, but I'm not the doctor who preaches—I'm the one who practices."*

Curbstone Consultation

QUESTION: What is the currently recommended treatment of superior sulcus or Pancoast tumors?

ANSWER: Superior sulcus tumors, first described by Pancoast, are peripheral bronchogenic carcinomas of the lung which invade the apical chest wall and produce a typical clinical picture of shoulder and arm pain, Horner's syndrome, and usually ulnar nerve paresthesia due to invasion of the brachial plexus. Rarely, other conditions such as tuberculosis or Hodgkin's disease may produce this picture. These tumors tend to progress slowly, locally, and to metastasize late.

The preferred treatment includes preoperative radiotherapy using a subcancerocidal dose of 3000 rads given in ten treatments over twelve days, followed in four weeks by en-bloc resection of the upper two to three ribs, apical segment or, generally, the upper lobe and if necessary any involved portion of the brachial plexus. The subclavian vessels can usually be preserved although resection of the artery with graft replacement has been carried out. Surgery is performed, however, only in the absence of metastatic disease as determined just prior to the scheduled date of operation. Occasionally, patients have shown the development of metastases during the four-week period following radiotherapy. The subcancerocidal radiodosage used tends to sterilize the periphery of the tumor and yet tends not to increase the operative complications as seen with higher dosages. Some workers advise against biopsy of the lesion, especially by thoracotomy, before initiating the radiotherapy, because of interference with the radioresponsiveness of the tumor due to the surgical reaction as well as an increased risk of dissemination of the tumor from this manipulation. These workers are willing to proceed with therapy on the basis of the typical clinical syndrome produced by these lesions and have found no consequence from the radiotherapy in the few cases where the cause of the syndrome was some other condition.

Needle biopsy of the lesion through the supraclavicular fossa may provide a pre-treatment diagnosis without as much interference with radioresponsiveness. With this combined therapy the survival rate has been significantly improved: an approximately 35 percent three-year survival; whereas formerly there were rarely any survivors at this time period following radiotherapy alone, surgery alone, or surgery plus postoperative radiotherapy.

Meetings and Announcements

American Medical Writers Association

The North Central Chapter of the American Medical Writers Association meeting November 1, 1969, 1:00 P.M., Judd Hall, Mayo Clinic, Rochester, Minnesota. Social hour and dinner, New Sheraton, Rochester, 7:30 P.M. All doctors interested in medical writing are welcome, wives included.

University of Minnesota

Medical Oncology Today

The University of Minnesota will conduct a course on October 8-11, for the American College of Physicians dealing with the application of Medical Oncology to clinical practice. The course will be aimed particularly at the practicing internist.

Automotive Medicine

The University of Minnesota will present a program dealing with medical aspects of automobile and other transportation injuries on October 16-18, 1969. This program is co-sponsored by the American Association for Automotive Medicine and should be of interest to all physicians dealing with trauma and other medical conditions resulting from transportation injuries.

Diabetes

The University of Minnesota will present a course in Diabetes Management and Control on October 22-24, 1969. The course will be co-sponsored by the Twin Cities Diabetes Association.

Urologic Radiology

The University of Minnesota will present a course in Urologic Radiology on October 27-31, 1969. For further information on all of the above courses contact: Lee D. Stauffer, College of Medical Sciences, Box 193 Mayo Building, University of Minnesota, Minneapolis, 55455.

Mayo Clinic Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery will be held at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Identical sessions are offered on November 3, 4, 5, 1969 and November 10, 11, 12, 1969.

This program is acceptable for credit by the American Academy of General Practice and the College of Family Physicians of Canada. The registration fee for this program is $20.

The number of physicians who can be accommodated is necessarily limited. For this reason identical programs will be offered two successive weeks. The program will be presented first on November 3, 4, 5, and repeated on November 10, 11, 12. Those wishing to attend should communicate with M. G. Brataas, Mayo Clinic, Rochester, Minnesota 55901, indicating which session they would prefer to attend.

The Viewing Box

Weakness and Backache

A 32-YEAR-OLD white female was admitted to the hospital complaining of weakness and backache on the left side. A routine urinalysis showed 10 to 15 red blood cells per high-power field; a repeat urinalysis three weeks later showed 60 to 75 red blood cells per high-power field. A chest x-ray showed a coin lesion in the right lower lobe. An intravenous pyelogram was done and suggested a deformity of the lower calyx of the left kidney.

Because of the history and laboratory findings a renal arteriogram was performed using 60% Hypaque (Figure 1). A tumor blush was suggested involving the lower pole of the left kidney (Figures 1 and 2). The findings, however, were inconclusive; so 12.5 micrograms of epinephrine were injected intra-arterially, with the catheter directed into the left renal artery. Sixty seconds later 8 cc. of 60% Hypaque were again injected through the catheter. Serial x-rays were taken which demonstrated an absence of small arterial branches in the left kidney, but a persistence of the fine arterial network distributed in the region of the lower pole (Figure 3).

What is your diagnosis? (See next page.)

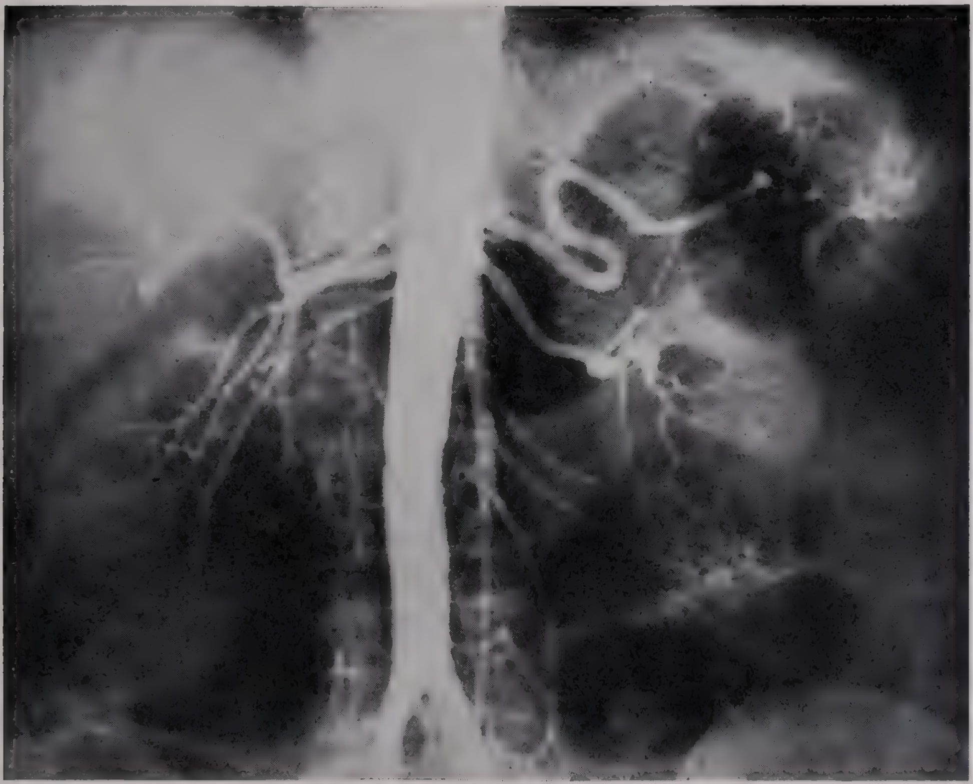

Figure 1

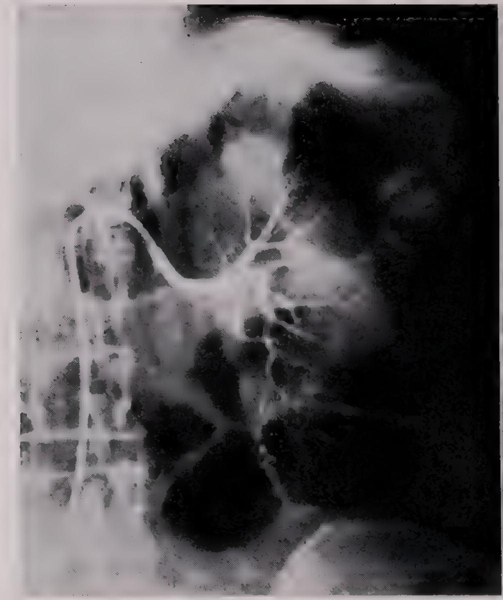

Figure 2

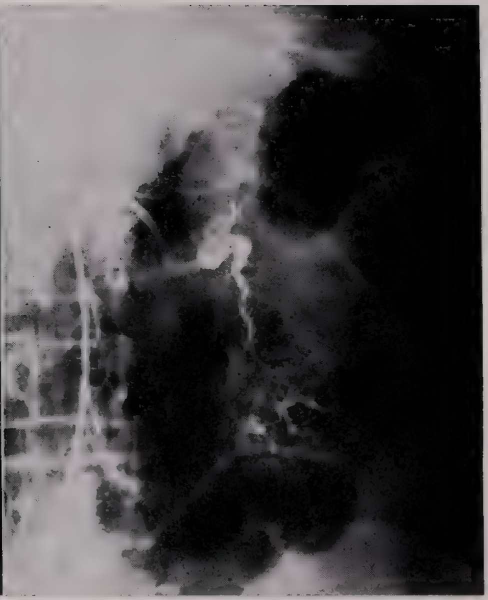

Figure 3

Diagnosis: Renal carcinoma of left kidney.

The patient underwent a left nephrectomy and a clear cell renal carcinoma of the lower pole of the left kidney was found. She made an uneventful recovery from her surgery with disappearance of her preoperative symptoms and hematuria. Four months postoperatively her chest lesion has shown no change, and it is planned to follow her at monthly intervals. A certain number of solitary pulmonary metastatic nodules from renal cell carcinoma will regress, or even disappear, after removal of the primary tumor. If the presumed metastatic pulmonary lesion does not regress or increases in size, excision will be advised.

The demonstration of a tumor blush by renal arteriography is convincing evidence of renal carcinoma. Abrams[1] devised a method for improving diagnostic accuracy in deciding whether or not a tumor blush exists by injecting epinephrine into the renal artery of the kidney in question. With this technique the small arterial branches supplying the normal renal parenchyma become obliterated, whereas the arterial networks supplying the carcinoma are unaffected. This serves to accentuate the radiographic appearance of the tumor blush on injection of contrast media by more blood being shunted through the arterial channels supplying the tumor as contrasted with those supplying the normal parts of the kidney.

The phenomenon of vasoconstriction of normal small renal arterial vessels by epinephrine while leaving unaffected the arterial supply to the neoplasm has also found application in treating renal tumors with cancer chemotherapeutic agents. By injecting epinephrine into the renal artery prior to injection of the cancer chemotherapeutic drug a situation results in which the blood supply is diverted from normal kidney to neoplasm. This results in a heavier concentration of the drug being delivered directly into the tumor mass.

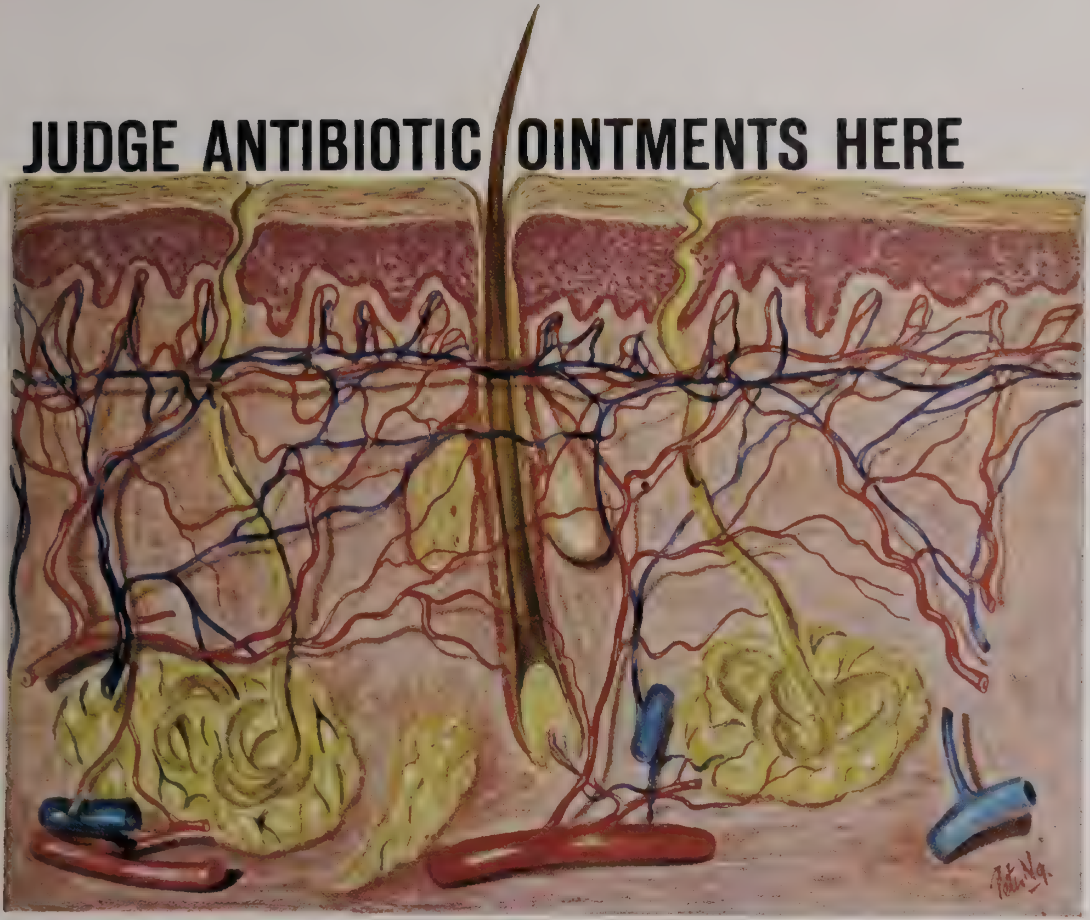
JUDGE ANTIBIOTIC OINTMENTS HERE



Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

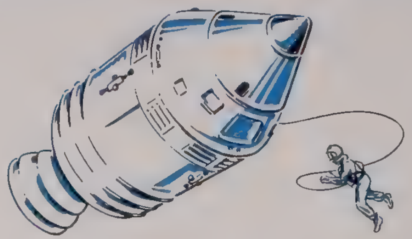
Art is a conception of peripheral vasodilation.



Man in space, now fait accompli, re-emphasizes the importance of Uro-Phosphate therapy. Research into the effect of space travel on the astronaut reveals that weightlessness causes loss of bone calcium. As the bones are required to bear less and less of the weight of the body they lose calcium, increasing the calcium content of the urine. When physical activity is reduced, the acidity of the urine should be adjusted to keep increased calcium in solution . . . . a prophylaxis to prevent kidney or bladder calculi.

Uro-Phosphate®

NOW A SUGAR-COATED TABLET

Each tablet contains: METHENAMINE, 300 mg.; SODIUM ACID PHOSPHATE, 500 mg.

Uro-Phosphate gives comfort and protection when inactivity causes discomfort in the urinary function. It keeps calcium in solution, preventing calculi; it maintains clear, acid, sterile urine; it encourages complete voiding and lessens frequency when residual urine is present.

Dosage:

For protection of the inactive patient 1 or 2 tablets every 4 to 6 hours is usually sufficient to keep the urine clear, acid and sterile.

2 tablets on retiring will keep residual urine acid and sterile, contributing to comfort and rest.

A clinical supply will be sent to physicians and hospitals on request.

Uro-Phosphate contains sodium acid phosphate, a natural urinary acidifier. This component is fortified with methenamine which is inert until it reaches the acid urinary bladder. In this environment it releases a mild antiseptic keeping the urine sterile.

Uro-Phosphate is safe for continuous use. There are no contra-indications other than acidosis. It can be given in sufficient amount to keep the urine clear, acid and sterile. A heavy sugar coating protects its potency.

Fracture Conference

Problems in Initial Treatment of Multiple Fractures*

Dr. Clarence R. Petrie:

After an automobile accident involving four teen-agers, all four were admitted simultaneously. We will present two of these cases because they represented challenging problems in the initial treatment planning for multiple fractures.

Case 1

The first case is that of a 17-year-old boy who was in the rear seat of a car that struck a bridge at an alleged speed of 90 miles per hour. During impact, he was ejected from the seat. In the emergency room, it was obvious that he had bilateral closed fractures of both femurs and an open fracture of the right ulna. Roentgenograms showed a comminuted midshaft fracture of the left femur with large butterfly fragments (Figure 1 left) and a severely comminuted midshaft fracture of the right femur with numerous splinter fragments (Figure 1 right). He also had a Monteggia type fracture of the right forearm (Figure 2), with the

---

*Fracture Conference held April 15, 1968.

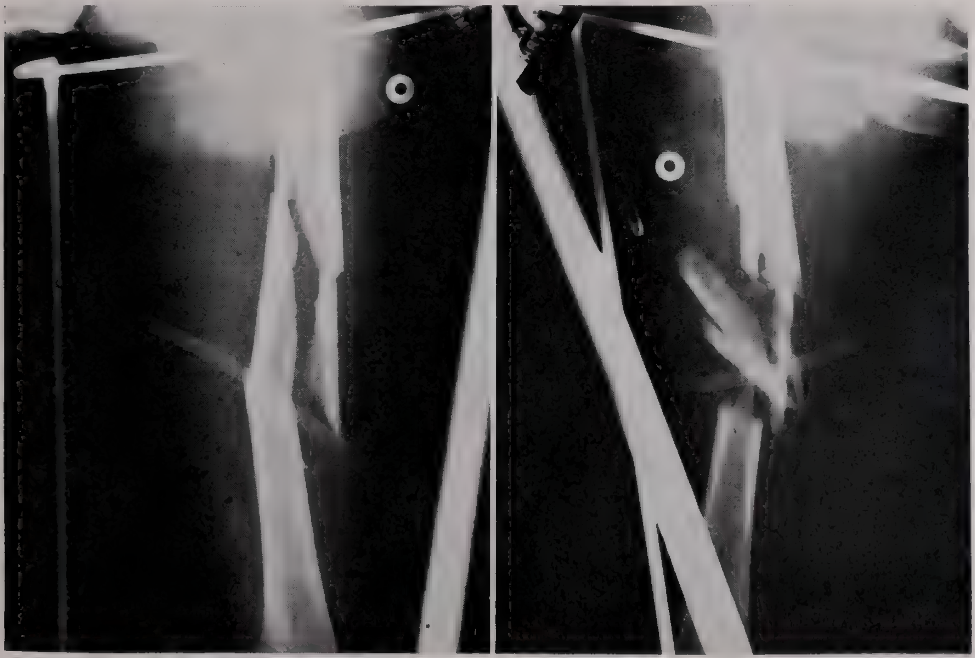

Fig. 1—(Case 1). Roentgenograms of femurs made in emergency room.

neck of the radius fractured rather than dislocated. A jagged laceration was present over the ulnar fracture site and extended up to the olecranon. In the femoral fractures, the soft tissue nerves and vessels were found to be intact.

The patient was in overt shock. With resuscitation well established, using blood and Ringer's lactate solution, he was taken to the operating room where, under general anesthesia, Steinmann pins were inserted into both tibial tubercles and traction was applied. The forearm wound was thoroughly cleansed and widely debrided, and the radius was examined. The annular ligament was found to be intact; therefore the head of the radius was left in situ. Internal fixation of the ulna was achieved by the insertion of a Rush intramedullary nail, which facilitated the reduction of the radial fracture as well. The arm was put in a Robert Jones dressing and the patient was taken to his room and placed in bilateral leg traction.

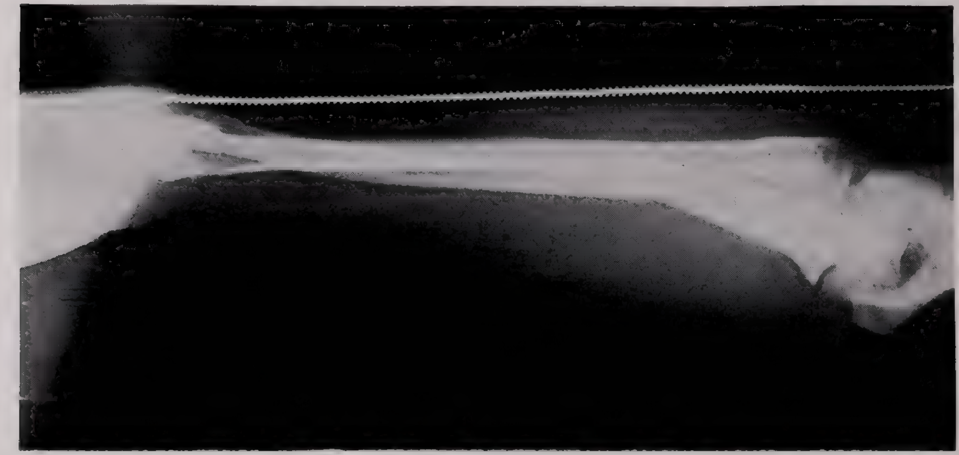

Fig. 2—(Case 1). Right forearm on admission.

Dr. Harry F. Jones:

The wound of the ulnar fracture was excised, debrided, and cleansed of all debris. Obviously dead material was removed, and then we proceeded to fix the fracture (Figure 3). The skin was packed open on the wound over the ulna. Now may I have some comments from the staff on these fractures of both femurs and the forearm. Dr. Coventry?

Dr. Mark B. Coventry:

When there are fractures of an upper and a lower extremity you really have more to worry about, because we hope eventually to have the patient ambulatory, and we would like to have a limb that can manipulate crutches. I think you have done the right thing in taking care of the forearm definitively and putting the femurs in traction with the patient in bed, perhaps starting him on anticoagulants, to wait it out in traction.

Dr. Jones:

It was my thought at the time that, if this had been a closed fracture, with everything else being equal, I would not have opened it. But, in a fracture like this in a boy of this age, one would probably have to open it sooner or later. I would have left it for two days or until things stabilized. When we saw him, he had lost a considerable amount of blood; but, once we got him resuscitated, we proceeded with the surgery.

Dr. Paul R. Lipscomb:

Dr. DePoali, who is visiting with us and has just finished two years in the

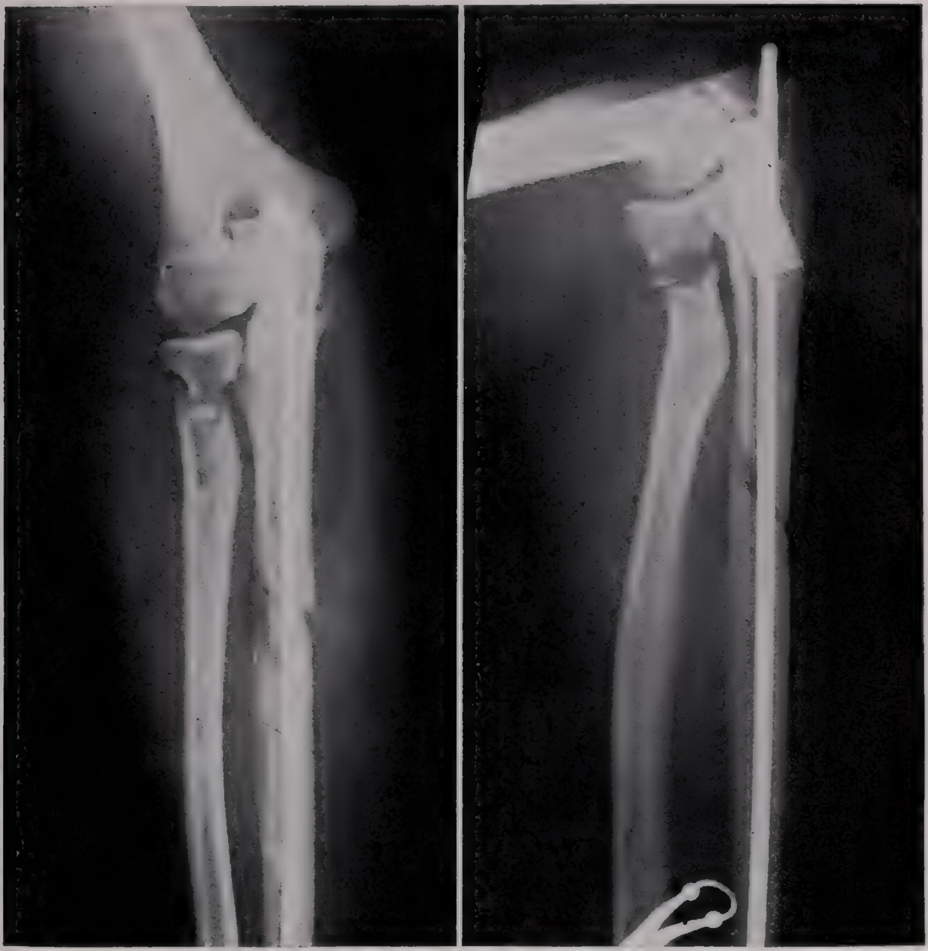

Fig. 3—(Case 1). Forearm after fixation of fracture.

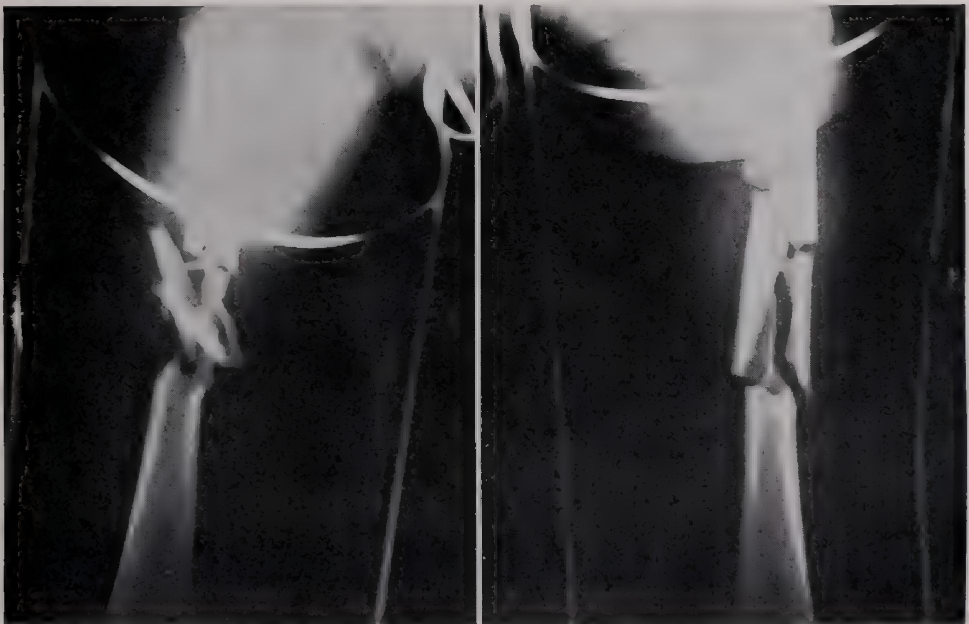

Fig. 4—(Case 1). Femurs after about three weeks in traction.

Army, made the point that if, in a case of fractures or multiple injuries like this, you can keep from giving a general anesthetic the situation remains clearer. For example, such things as a ruptured spleen may be hidden by a general anesthetic. It may have been safer to do this under axillary block and insert the pins under local anesthesia, even if it would have taken time.

Dr. Jones:

I would agree with this; but at that time it was 2:00 or 3:00 a.m. and the anesthesiologist thought it better to have the patient asleep than to do this under a block. I would personally agree entirely with you. I wonder if I could get some views on whether or not we should have excised the head of the radius.

Dr. Ronald L. Linscheid:

I would not particularly want to excise the radial head. I have treated some injuries like this in which, even if you do have a stable ulna, you get some angulation at the fracture site in the radial head. Because this has happened to me, I would probably transfix that radial head with a Kirschner wire through the distal humerus.

Dr. Jones:

I felt this radial head with my hand. The annular ligament was entirely

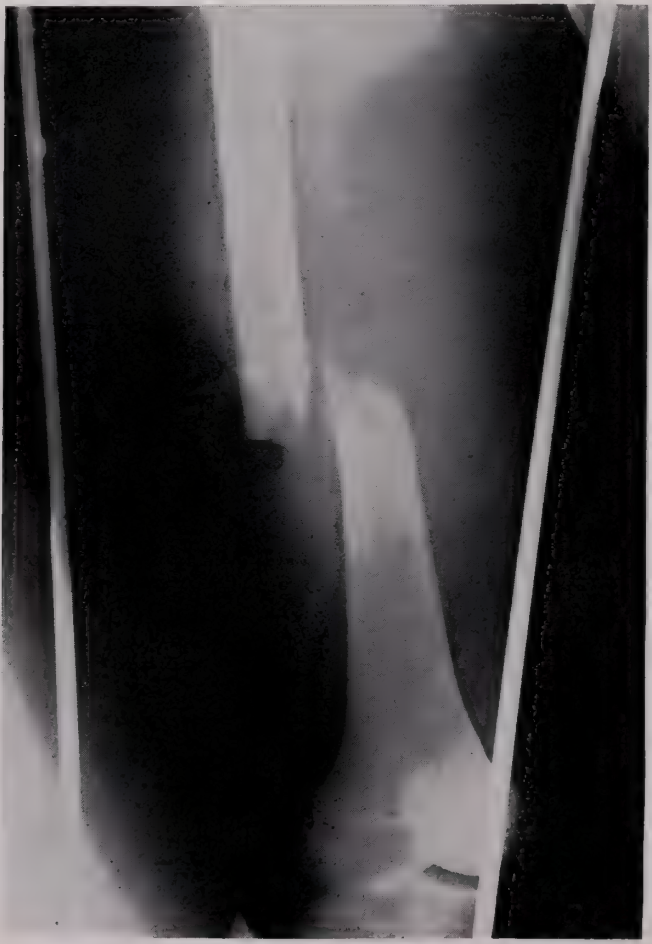

Fig. 5—(Case 2). Right femur on admission.

intact—it had not been injured at all—and at the time the situation seemed to be safe from late dislocation.

Dr. Einer W. Johnson, Jr.:

We have mentioned this before and I think it should be mentioned again that the thorough debridement of the compounding wound is essential. If this fracture had become infected, you would have had serious trouble. I personally think that it is correct to pack the wound open, as you have done, and proceed with delayed primary closure or secondary closure at some future date when you know you have good control of whatever bacteria may be there. It seems to me you have lost nothing by doing it this way as compared to closing the wound primarily, even though antibiotics are available to help you. Primary closure is recommended by some. I think it is far better to pack it open and close it at another time.

Dr. Jones:

I do not think anyone would close a very dirty wound in a case like this. This boy was thrown down an embankment into the mud and dirt, and the wound was quite a mess when he arrived. These roentgenograms of the femurs in traction were made about three weeks postoperatively (Figure 4).

Dr. Coventry:

I would like to comment on what Dr. Lipscomb said about initial shock. To make it a little more complete, do not forget the fat embolism problem which is always a potent one in multiple injuries 24 or 48 hours, and even three or four days later. The initial anesthesia can mask or even aggravate that embolism. So it is not only shock but also fat embolism you have to contend with.

Dr. Petrie:

Case 2

A 17-year-old boy was the driver of this automobile when it struck the bridge. He was not thrown out of the car but was pinned and had to be removed forcibly. On examination in the emergency room, he was in shock; he had an open fracture of the midshaft of the right femur with loss of overlying tissue, and the proximal fragment protruded from the wound. This can actually be seen on the roentgenogram (Figure 5). He also had a closed fracture of the left forearm involving the distal third of the ulna and the middle third of the radius (Figure 6).

The patient was resuscitated and, when hemodynamic stability was attained, was taken to the operating room for wide debridement of the thigh wound and internal fixation by the use of a Mueller compression plate (Figure 7 left and center). The wound was packed wide open

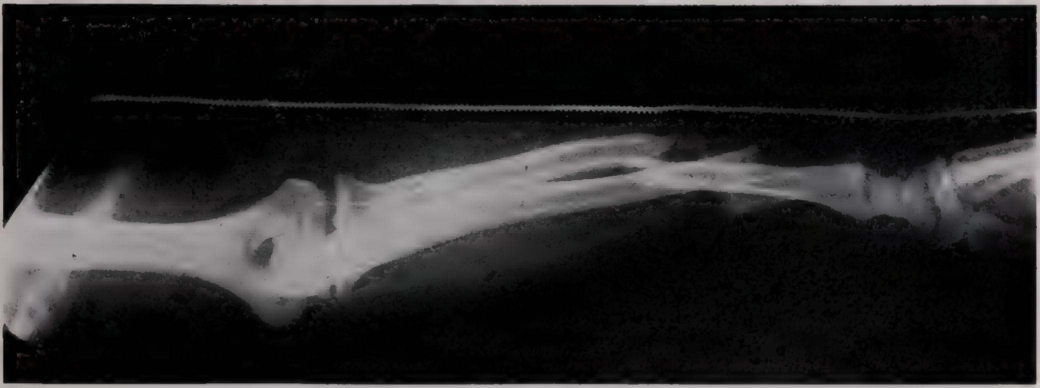

Fig. 6—(Case 2). Left forearm on admission.

and dressings were applied. We then proceeded to do open reduction and internal fixation of the left forearm. Mueller compression plates were applied to both ulna and radius (Figure 7 right). The left forearm was severely swollen and was placed in a Robert Jones dressing with a Bunnell dressing on the hand.

Two days postoperatively the patient was returned to the operating room and the thigh wound was inspected and found to be clean and noninfected. It was repacked. Five days postoperatively the thigh wound was once again inspected. In the interim there had been no evidence of infection and the wound was found to be clean. Due to soft tissue loss at this site, local skin flaps had to be mobilized to close the soft tissue defect (Figure 8). Fifteen days postoperatively the wound was again inspected and once again there was no evidence of infection. A hip spica was applied and the patient was dismissed, to return in six weeks for reassessment.

Dr. Jones:

In my opinion the wounds were well healed. I wonder if Dr. Coventry would like to comment on this case?

Dr. Coventry:

I think you have done what I would do. You have a wound that was compounded. This alters your plan of treatment. You have to get at the wound, and while you are in there, I have always found that there is no added risk, and it certainly is a tremendous boon to the patient, if you can secure the fracture at the same time. Providing everything else is equal, putting a plate and

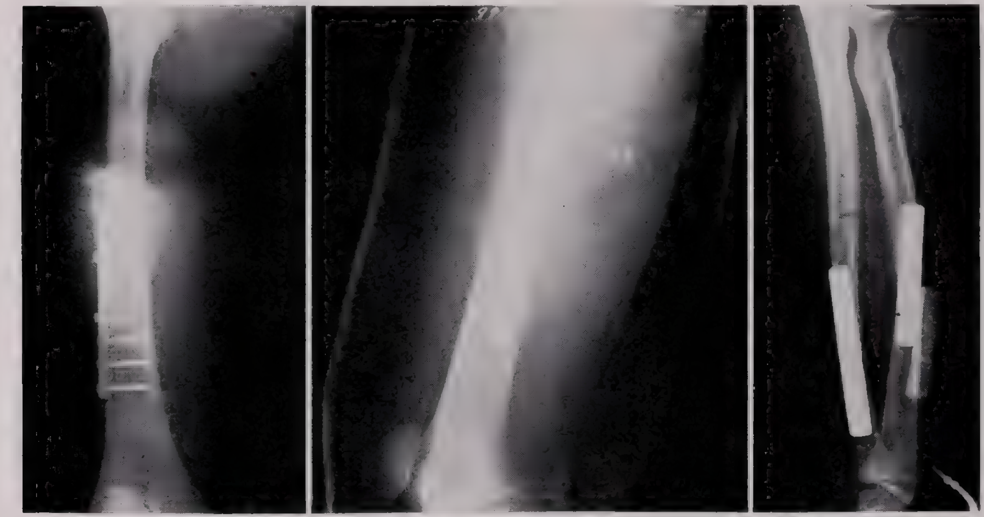

Fig. 7—(Case 2). After application of Mueller compression plates. Left and Center, Femur. Right, Forearm.

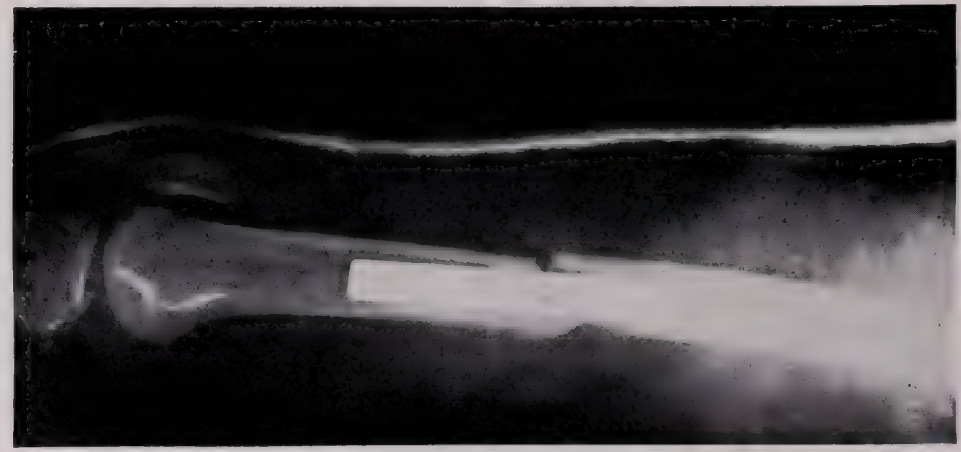

Fig. 8—(Case 2). Femur five days postoperatively, at time of wound closure.

screws into an acute fracture is no offense and is a very good way to avoid a bad situation for the patient.

Dr. Jones:

I spent two and a half hours debriding the patient's wound and 15 minutes applying this plate. I think it would be wrong if it were the reverse. This wound was either going to become infected or it was not going to become infected. The addition of a plate, as far as I was concerned, did not endanger the situation. I think the thoroughness of the debridement was the important thing.

Dr. Richard S. Bryan:

As a point of criticism on the technique of insertion of the Mueller compression plate I should like to state that the distal compression screws should not go through both cortices. You run a risk of fracture at that point, which should be avoided. You need only one cortex for application of the compression apparatus.

Dr. Jones:

I am aware of this.

Dr. Bryan:

Second, with reference to the plating of forearm bones, there are a number of articles in the English literature which criticize the use of these four-hole plates. I tend to use them, but I think the opponents make their point. Use of three screws on each side gives a lot more fixation than two, and your fulcrum screw on the radial fracture appears to be almost in the fracture itself.

Dr. Jones:

Even though this fracture is pretty far distal on the shaft, we had a problem attaching even this size of plate.

Dr. Bryan:

You could have gotten three screws on that one going down the radial shaft. It could be a little difficult, but it would be possible. The English are critical of using less than six screws. This is the third point: they may be right and they may be wrong, but it is a point to consider. It appears that there is not much compression on the radius.

Dr. Jones:

There is no compression on that at all. I ran into a situation in this fracture which never happened to me before, but I put the Rush pin down the ulna and the compression plate on the radius. However, for some reason or other, we got off track and the Rush nail penetrated the ulnar cortex. Try as I might, I could not get the nail to return in the right direction. It was then that we decided to plate this bone also.

Dr. William H. Bickel:

Another point Dr. Mueller makes is that the end screws in the plate—this would have to be in a six-hole plate—should not go through both cortices because some pathologic fractures occur when the screws are put through both cortices. It is all right to put a longer flare on the end of the plate or to put a screw through one cortex.

Dr. Bryan:

One last point, so that somebody can come back and step on me: Why did you not put two plates on the femur?

Dr. Jones:

I really did not think that I needed to. It was stable as a rock the way it was. I thought that if it did get infected I would have to remove the plate. I did not put this boy in a spica cast or anything; I put him in a Robert Jones dressing, in which he remained for approximately 15 days while we were observing his wounds. There was no problem whatsoever with instability. He was moved from a cart to the bed and was frequently on a bedpan. All I can say is that at operation I thought this fracture was compressed sufficiently.

Dr. Bryan:

From looking at the roentgenograms, you are not sure how far the screws go through, or of the even seating of the screw heads. This I have found myself: I measure them, I put them in, and I think I have beautiful fixation; then I look at the postoperative roentgenograms and wonder why I did not make that a quarter, or at least an eighth, of an inch longer. I am sure that I measured it as carefully as I could and got as excellent fixation as possible. Once in a while the fixation will fail; then we regret it about six to eight weeks later.

Dr. Johnson:

These last two cases represent a problem in the initial treatment in the trauma of these two boys. They were both in a serious automobile accident. The point I would like to make is that I think you glossed over the principal problem: the prevention of infection. Had either of these wounds become infected, you would have been in deep trouble. You stated briefly that you spent two and a half hours debriding the wound and 15 minutes applying the plate. It should be reiterated that you did a thorough wound toilet, which is to be expected, but we must emphasize that point. We have often seen wounds treated elsewhere that are not well debrided and come to us dirty. The thing to be striven for in these cases is wound toilet, excellent debridement, and healing without infection.

Dr. Jones:

One other point I should have brought out more clearly is that I consider this a staged debridement. You debride it initially and then again at two days, at four days, and, if necessary, at six days. You have to evaluate such a wound every other day, or every day, depending on how you do it. I do not think anyone can look at a wound and say, "Now I have thoroughly debrided that," or "There is no more devitalized muscle, skin, or bone, or some such thing." We returned this boy to the operating room, did a full preparation and scrub, and thoroughly examined this wound inside and out rather than just glancing at it on the ward and saying it looked clean.

Dr. Johnson:

This is the point that I consider interesting.

Dr. Jones:

Our time is up. These cases illustrate the problems in initial care of the multiply-injured patient—attention to proper resuscitation and control of shock, definitive care only when the patient is hemodynamically stable, and, probably most important of all, thorough debridement and cleansing of compound wounds.

Memory Aid

"Doctor," she says, "I have written a list
Of my symptoms, for fear I'd forget them.
They're here in my bag, if I only can find
The paper on which I have set them.

"Yes, here they are, doctor; I have here the list
Of the things that I've carefully noted:
A pain that begins in the small of my back
And my being so terribly bloated,

"And a dozen loin chops and it hurts me to breathe
And a couple of pounds of tomatoes
And a rash on my chest and a small piece of cheese
And chills and a sack of potatoes."

Richard Armour: The Medical Muse, 1963.

Objective vs Subjective

If the sense of sight is more objective, the sense of hearing is more subjective, and it is through this latter sense, by means of dialogue, that the physician's "I" merges with the patient's "you," as von Weizsacker pointed out. This is why the clinical case history achieved in such a manner has the same value that experimental observations have in the natural sciences. Every disease is eminently biographical, even infections and degenerative organic affections, and its configuration, or Gestalt, depends not only on the biological dimension of the individual biography, but on the totality of the biography, on the personal dimension of human existence.*

*The Patient's Progress, Edited by Felix Marti-Ibanez, M.D., 1962.

Worry

Now psychologists think they have found what professional people worry about. At the age of 26, they say, the principal worry is about making a good impression on people, at 30 about job security and economic problems, at 38 about health and at 41 about politics. At 42 marital problems are in the fore, and by 45 professional men and women concentrate on worrying about giving up lifelong ambitions. After that, health again becomes the chief preoccupation.

—National Parent-Teacher.

THE BREAKUP of a business partnership, the crack-up of a marriage, the shake-up of being fired or reduced to bankruptcy…after any significant loss or severe blow to self-esteem, *both* anxiety and depression almost always follow.

FOR MODERATE TO SEVERE ANXIETY WITH COEXISTING DEPRESSION

TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

Containing perphenazine and amitriptyline HCl

For prescribing information, including indications, contraindications, warnings, precautions, and side effects, please see following page.

FOR MODERATE TO SEVERE ANXIETY WITH COEXISTING DEPRESSION

TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

Containing perphenazine and amitriptyline HCl

TRIAVIL®2-25: Each tablet contains 2 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.

TRIAVIL®4-25: Each tablet contains 4 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.

TRIAVIL®2-10: Each tablet contains 2 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

TRIAVIL®4-10: Each tablet contains 4 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

INDICATIONS: Patients with moderate to severe anxiety and/or agitation and depressed mood; patients with depression in whom anxiety and/or agitation are severe; patients with depression and anxiety in association with chronic physical disease; schizophrenics with associated depressive symptoms.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; urinary retention; pregnancy; glaucoma. Do not give in combination with MAOI drugs because of possible potentiation that may even cause death. Allow at least 2 weeks between therapies. In such patients therapy with TRIAVIL should be initiated cautiously, with gradual increase in the dosage required to obtain a satisfactory response.

WARNINGS: Patients should be warned against driving a car or operating machinery or apparatus requiring alert attention, and that response to alcohol may be potentiated.

PRECAUTIONS: Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having various modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Not recommended for use in children. Mania or hypomania may be precipitated in manic-depressives (perphenazine in TRIAVIL seems to reduce likelihood of this effect). If hypotension develops, epinephrine should not be employed,as its action is blocked and partially reversed by perphenazine. Caution patients about errors of judgment due to change in mood.

SIDE EFFECTS: Similar to those reported with either constituent alone.

Perphenazine: Should not be used indiscriminately. Use caution in patients with history of convulsive disorders or severe reactions to other phenothiazines. Likelihood of untoward actions greater with high doses. Closely supervise with any dosage. Side effects may be any of those reported with phenothiazine drugs: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); extrapyramidal symptoms (opisthotonos, oculogyric crisis, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; severe acute hypotension (of particular concern in patients with mitral insufficiency or pheochromocytoma); skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; endocrine disturbances (lactation, galactorrhea, disturbances of menstrual cycle); grand mal convulsions; cerebral edema; altered cerebrospinal fluid proteins; polyphagia; paradoxical excitement; photophobia; skin pigmentation; failure of ejaculation; EKG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in the pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia; significant unexplained rise in body temperature may suggest intolerance to perphenazine, in which case discontinue. Antiemetic effect may obscure signs of toxicity due to overdosage of other drugs or make diagnosis of other disorders such as brain tumors or intestinal obstruction difficult. May potentiate central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol), atropine, heat, and phosphorous insecticides.

Amitriptyline: Careful observation of all patients recommended. Side effects include drowsiness (may occur within the first few days of therapy); dizziness; nausea; excitement; hypotension; fainting; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of latent schizophrenia (however, the perphenazine content may prevent this reaction in some cases); epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration, or transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of mouth, blurring of vision, urinary retention, constipation, paralytic ileus; agranulocytosis; jaundice. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Case Reports

Corrosive Esophagitis

Acute Management with a Case Report of Early Surgical Intervention

Case Report

A 41-YEAR-OLD paranoid schizophrenic patient was transferred to Minneapolis Veterans Administration Hospital for management of an acute corrosive esophagitis following an attempted suicide by lye ingestion the evening prior to his transfer. On admission he was found to have a severe burn of both the anterior and posterior oral cavity. Treatment was initiated with antibiotics and steroids; a small feeding tube was passed and a tracheostomy was performed. Within 24 hours of admission, substernal pain and a chest x-ray led to the diagnosis of esophageal perforation with mediastinitis and empyema. Approximately 60 hours following the lye ingestion, surgical exploration revealed his esophagus to be necrotic from the level of the second tracheal cartilage to the gastroesophageal junction and his stomach necrotic over the proximal 80%, with several areas of necrosis. An area of perforation of the esophagus into the right pleural cavity was found, and 2.5 liters of fluid were drained from the right pleural and peritoneal cavities. A subtotal gastrectomy, a total esophagectomy, with cervical esophagostomy, and a gastrostomy were performed. The patient tolerated the procedure well. He continued to have a low-grade fever but showed overall improvement until the sixth post-operative day when he suffered a massive hemorrhage and expired. Post-mortem examination showed a suppurative mediastinitis with massive great vessel hemorrhage as the cause of his demise.

Etiology

Corrosive esophagitis appears as the result of the ingestion of some irritating acid or alkali with a frequency[31] of 8.9/100,000 general hospital admissions. It has a higher incidence[14,31] among the lower income groups, the southern states and the negro population. It is seen more frequently below the age of 15, with a greater proportion of males than females; but within the adult population there is an equal distribution between the sexes, the female suicides matched by the male "alcoholic accidents." The agents commonly involved include[33]: NaOH, KOH, phenol, ammonia, formaldehyde, lysol, sulfuric acid, nitric acid, lactic acid, potassium, permanganate, iodine and bichloride of mercury. Lye (NaOH) is[23] the most frequent offender and the most serious, for while acid will produce a coagulative necrosis leading to early eschar formation, alkali, due[31] to its hydroscopic, saponifying, and protein solvent properties, will produce a liquefying necrosis enabling penetration to deeper layers.

Pathology

The severity of the lesion produced depends[10,34] directly upon the corrosive agent swallowed: its nature, concentration, quantity and the duration of its contact with the tissues. A 3.8%[9] (1 N) solution of NaOH applied for 10 seconds to the esophagus will necrose the mucosa, the submucosa, and some of the inner longitudinal muscle fibers, while a 22.5% (7 N) solution in the same time will extend necrosis through the whole esophageal wall and affect the periesophageal tissues. The significance of these values is obvious when it is realized that household cleaning and washing powders typically have from 8 to 50% NaOH as their chief ingredient.

The usual[34] areas of esophageal involvement are the cricopharyngeus, the crossing of the left main bronchus and the cardia. The upper esophagus is the most frequently involved, while the lower esophagus is usually the most seriously involved, presumably due to reflex spasm at the cardia. The lesion develops in a characteristic sequence[3,5,14]: within the first 24 hours there develops epithelial destruction, edema and congestion of the entire wall. Within 48 hours this inflammatory infiltrate leads to thrombosis of submucosal, vessels, giving rise to local areas of gangrene with sloughing of the surface layers. Bacterial invasion follows, leading to intramural abscess formation and final chronic inflammatory change. Re-epithelialization is often incomplete at six weeks, while stricture formation is discernible after the second week.

TABLE

Complications of the Injury

Acute Phase:[30]		Late Phase:[6]
Mediastinitis	20%	Stricture
Ulceration into aorta or trachea	20%	Perforation of the esophagus (secondary to esophagoscopy or dilatation)
Perforation of the esophagus	15%	Aspiration pneumonia
Peritonitis	15%	Operative risk from reconstructive surgery
Bronchopneumonia	14%	Carcinoma from the old stricture line[33,6,7]
Perforation of the stomach	10%	
Edema of the larynx	6%	
Acute Mortality is Variously Reported:		
Holinger and Johnston[15]	3.1%	
Stumboff[30]	27.0%	
Hung et al.[17]	36.6%	

Treatment

The management of corrosive esophagitis remains controversial. Treatment generally depends[9] upon the severity of the burn, the systemic reaction to the injury and the complications that develop. Proper therapy[9] includes an initial control of shock, restoration of electrolyte balance, maintenance of nutrition, antibacterial therapy, and ultimately, a repair of the esophageal lesion itself.

Acute Phase

Attempt Neutralization

(1) Alkali by 2% acetic acid, vinegar or citrus juices. (2) Acid by olive oil, milk, magnesium oxide or egg white (not $NaHCO_3$, because the gas formed will stimulate distention and vomiting). (3) Gastric lavage in acid ingestion (contraindicated in alkali ingestion). However, it has been shown[10] that attempts to neutralize later than one minute after ingestion of the offending agent had no effect on the clinical course of the patient, and even within one minute, it did not prevent injury to the tissues.

Treat Tracheostomy

Indicated to maintain ventilation in increasing laryngeal edema.

Put Esophagus at Rest

(1) Discontinue all oral feedings. (2) A small feeding tube may be introduced[13,29] to maintain a patent lumen and provide a route for nourishment, but some[10] feel the increased trauma of the tube and its stimulus to nausea and vomiting contraindicate its use.[10,33,34] (3) A gastrostomy may be created to provide nourishment.

Antibiotics

To control secondary infections and reduce scarring one million units of penicillin and one gram streptomycin per day have been used.[9] However, reports[19] indicate the antibiotics promote early granulation tissue and hasten its maturation, resulting in earlier stricture formation.

Steroids

To reduce inflammation and subsequent scarring, use of cortisone equivalent to 420-560 mg/day for a 70-kilo human has been shown[27] to reduce scarring, and prednisone at 4 mg/kilo in divided doses has been successfully used clinically.[19,9] However, these steroids must be used less than 48 hours after the insult and preferably less than 24 hours to prevent scarring.[27,34] The steroids in decreasing inflammation tend to increase the incidence of suppurative infections and must always be used in conjunction with antibiotics.[26,27,28] Steroids further (even with antibiotics) tend to increase the incidence of perforation and hence are contraindicated in very severe burns and in gastric ulcerations.[28]

Anticholinergic agents and antacids are recommended in steroid therapy.[28]

Daily x-rays of the mediastinum (for the first two weeks) for early detection of perforation are recommended in steroid therapy.[28]

Patent Lumen

A string can be swallowed to maintain a patent lumen and to act as a guide for examinations or dilatations.[33]

Symptomatic Relief

H_2O_2 oral care; medications for relief of pain; olive oil and other soothing agents may be sipped cautiously.

Intermediate Phase

In the intermediate phase, therapy is directed to the prevention of contracture. There generally are three approaches to the problem.[33] 1) Early dilation to prevent collagen fiber contracture: (Salzer, Bokay, Martin and Arena, Gellis and Holt, Crowe, Kernodle, and Holinger). 2) Dilation after contracture has started to form: (Stumboff, Vinson). 3) No dilations in the belief that all established strictures of the esophagus are surgical problems: (Burford).

Late Phase

Treatment in the late phase involves the restoration of esophageal function by the relief of strictures that have developed. There are several techniques available: Blind bouginage, direct bouginage (using Jackson dilators) through an esophagoscope, bouginage over a string guide, retrograde bouginage utilizing a gastrostomy and "endless string," pneumatic bougies placed under fluoroscopic control, and surgical restoration of the damaged tract.

Comment

This case in unusual in that it represents an attempt at early, radical, surgical treatment for corrosive esophagitis. In retrospect it is apparent the esophagus was non-viable and the only possible treatment was the removal of the necrotic tissue; it is unfortunate this was not realized earlier. Contamination of the mediastinum (perforative[4,11,14,20] or otherwise[18]) with subsequent suppuration has an untreated mortality[11] of 84% that can be reduced by surgical intervention to 15 to 30%. Such values demonstrate the place for early consideration of such surgery in those patients whose injury is so severe as to preclude a more conservative therapeutic regime. In these select cases, this early radical surgery may be life preserving and should consequently be given careful consideration.

NONINSTRUMENTAL PERFORATIONS OF THE ESOPHAGUS

Perforations of the esophagus often lead to a high morbidity and mortality, particularly when recognized late. A 30% mortality is reported among the series of 22 patients with noninstrumental perforation of the esophagus. Perforations due to injection of a sharp foreign body responded well to treatment, whereas spontaneous postemetic perforation and rupture of the esophagus carry an extremely grave prognosis, with six to eight patients succumbing to this disease. Treatment of the foreign body perforations of the cervical esophagus consisted of removal of the offending foreign body and occasionally cervical drainage. Treatment of the postemetic thoracic esophageal perforation included surgical drainage and attempts at closure of the esophageal perforation.

Adam R. Wychulis, M.D., et al.: Noninstrumental Perforations of the Esophagus. Dis Chest 55:3:190, 1969.

THERMOGRAPHY IN BREAST CARCINOMA

Isard et al. have studied a large series of women constituting approximately 2700 patients in whom thermograms were carried out. The tests were negative in 69 percent and positive in the rest.

The significant finding seems to be that in the proven malignant lesions thermograms were positive in 72 percent, whereas in the benign group they were positive (incorrectly diagnostic) in 61 percent.

From this the authors justifiably concluded that they were "unable to differentiate the benign from the malignant pattern by this technique."

In using the thermogram technique, however, it might be favorably said that "any departure from the baseline pattern of an individual should serve as a warning for some disease process."

Only for an institution or an individual who is carrying out a large series of breast examinations serially would it seem economically and scientifically feasible to institute this type of laboratory evaluation.

Carl O. Rice, M.D.

INSTRUMENTAL PERFORATION OF ESOPHAGUS

Esophageal perforation occurred in 33 of 8,038 patients who underwent gastrointestinal endoscopic procedures at Mayo Clinic (0.4%). The percentage for patients undergoing the esophagoscopy was 0.8%. Perforations of the cervical portion of the esophagus were more common but less serious than those of the thoraco-abdominal esophagus. Perforations occurred most commonly at the site of either benign or malignant esophageal strictures and were most frequently caused by excessive dilatation without satisfactory guide, bougienage or biopsy, but beyond visual range. The most helpful diagnostic tests were x-rays of the neck or thorax. Results were best when treatment was initiated promptly and pursued aggressively with use of antibiotics, surgical drainage and elimination of esophageal obstruction.

**Painful night leg cramps...**

unwelcome bedfellow for any patient–
including those with arthritis, diabetes or PVD

One thing patients can sleep without, particularly patients with chronic disease conditions such as arthritis, diabetes or PVD, is painful night leg cramps. Although seldom the presenting complaint, night leg cramps can tie your patients up in painful knots. Now, just one tablet of QUINAMM at bedtime can usually bring an end to shattered sleep and needless suffering. Your patients will sleep restfully—gratefully—with QUINAMM, specific therapy to prevent painful night leg cramps.

Quinamm™ Specific therapy for night leg cramps
(quinine sulfate 260 mg., aminophylline 195 mg.)

Prescribing Information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Trichomonads...Monilia...Bacteria

You can depend on AVC — the comprehensive therapy that acts against all three major vaginal pathogens.

Monilia emerging as a major therapeutic problem —

recent studies report increased incidence, attributed in part to the use of oral contraceptives,[1-4] broad-spectrum antibiotics[5-9] and prolonged use of corticosteroids.[7]

recent evidence establishes high rate of microbiological and clinical cure with AVC.[9-11]

Comprehensive — Effective

The published record and more than two decades of clinical experience clearly establish the therapeutic value of AVC in vaginitis/cervicitis and vaginal surgery.

Easy as AVC

Contraindications: Known sensitivity to sulfonamides.

Precautions/Adverse Reactions: The usual precautions for topical and systemic sulfonamides should be observed because of the possibility of absorption. Burning, increased local discomfort, skin rash, urticaria or other manifestations of sulfonamide toxicity are reasons to discontinue treatment.

Dosage: One applicatorful or one suppository intravaginally once or twice daily.

Supplied: Cream — Four-ounce tube with or without applicator. Suppositories — Box of 12 with applicator.

Dermatology

Cutaneous Biopsy

The cutaneous biopsy is often of great help in either establishing or confirming a diagnosis. Its use is not limited to potentially malignant skin lesions; it also may be of considerable help in diagnosing various skin diseases of diverse causes. Unlike biopsies from other organs, the skin biopsy specimen is easily and quickly removed in the office with a minimum of discomfort to the patient. Rarely is it necessary to excise with the scalpel. The necessary equipment is present in the office of most practitioners. Local anesthesia may be achieved easily by lidocaine (Xylocaine®). However, if the patient is allergic to this type of drug, satisfactory local anesthesia may be achieved with ethyl chloride spray or an antihistamine (intradermal).

Obtaining the specimen is greatly facilitated by the use of a skin biopsy punch which resembles a cookie cutter and is used in much the same manner (Figure). The instrument comes with circular blades of various diameters, probably the most practical being the 4 or 5-mm size. On the face it may be best to use the 2 or 3-mm punch. With these sizes scarring is generally inconsequential. However, it is not necessary to use this instrument in order to obtain a suitable specimen. A fine iris scissors and small single toothed forceps can be used very nicely in performing a small cutaneous biopsy. Circumscribed tumors (verrucae, seborrheic and actinic keratoses) can be re-

Figure

moved with facility by curettage. If the biopsy site is not on a conspicuous location, suturing is usually not necessary; pressure or light electrocautery suffices to produce hemostasis in most instances, and healing is rapid.

Fixation of the specimen may be achieved with 10 percent formalin (4 percent aqueous solution of formaldehyde). It is best to allow the specimen to remain in the formalin at room temperature for six hours before shipping, especially if the weather is cold. In winter, if the specimen is to be mailed, 70 to 90 percent ethyl alcohol may be used as the fixative. Both formalin and alcohol have the disadvantage that fat is lost during fixation. The amount of fixative should approximate 20 times the specimen by volume.

The site from which the specimen is taken is important in getting the most information. Selecting a characteristic lesion from a commonly involved location is desirable. Depth is also important; if the disease has no induration, a specimen including most of the dermis is usually adequate. However, if a deeper process is clinically evident, such as a panniculitis* or nodular lesions of the lower extremities, then subcutaneous tissue should be included. This latter type of biopsy usually requires scalpel excision with sutures.

Timing can be important in performing the skin biopsy. For example, in vesiculobullous diseases early unruptured (not older than 24 to 48 hours) lesions taken out intact usually give the most information. If there are stages in the evolution of an eruption, it is best to choose a well developed lesion or two lesions of different stages. Also, if the condition has multiform characteristics, the physician may have to remove several specimens in order to gain the information he desires. This also is true in large ulcers where one wishes to exclude carcinoma by taking several specimens from indurated sites at the periphery.

When submitting the specimen it is important to include: the patient's name, age, sex, site of the biopsy, duration of the eruption or lesion, brief clinical description, and diagnostic possibilities. When sending the specimen to a general pathologic laboratory the physician should be sure the laboratory is willing to accept and process small cutaneous specimens. Many non-dermatologic laboratories are geared for larger surgical specimens, a routine which may cause excessive artifactual change in 2 to 6-mm sections.

The cutaneous biopsy is most useful in the identification of cutaneous cancer of various types, precancerous lesions, and a number of cutaneous diseases whose histopathology is characteristic. Even when not diagnostic, the cutaneous biopsy may be very helpful in differentiating other conditions whose pathology is characteristic. Other areas where the biopsy is helpful include bacterial and mycological infections where special stains may identify the organisms. In metabolic and other systemic disorders the skin is frequently involved, and here histochemical techniques as well as histopathology may help in arriving at a diagnosis. Biopsy does not always give a definite diagnosis; however, its use should be encouraged, for the information obtained may be of great help in the management of many dermatologic problems.

Grand Rounds

Hypercalcemia Associated with Non-Parathyroid Tumors

RICHARD R. STURGEON, M.D.
Minneapolis, Minnesota

Case Report

The patient, a 71-year-old white male, had enjoyed generally good health until six months prior to admission, when he had an insidious onset of hoarseness, cough and chest pain. He was noted to have a right vocal cord paralysis at that time, but he refused further evaluation. He complained of weakness and difficulty swallowing during the five weeks prior to admission. He had also noted an enlarging mass in his neck.

On examination he was lethargic, with a hoarse voice, mild tachypnea, and a productive cough. There was a slightly tender, hard, fixed, three-centimeter paratracheal mass in the right suprasternal area, which was displacing the trachea markedly toward the left and appeared to extend into the superior mediastinum. There were findings of right lower lobe consolidation and guaiac-positive stool. He was noted to have hypoactive reflexes.

A chest roentgenogram showed a right lower lobe infiltrate with effusion. An electrocardiogram was normal with a QT interval of 0.38 seconds; Hgb. 13.8 Gm., WBC 12,000/mm^3, BUN 17 mg.%; albumin 2.8 Gm.%, alkaline phosphatase 12 K-AU., calcium 13.8 mg.%, phosphorus 2.9 mg.%. A sputum culture grew a mixture of gram-positive organisms.

The patient received intravenous antibiotics and fluids, as he could not maintain his hydration orally. A bone survey was negative, BSP retention 15% at 45 minutes. Urine: calcium 424 mg. in 24 hours, phosphorus 412 mg. in 24 hours, creatine clearance 30 cc/min. (Calcium free diet). PBI and T_3 were normal.

The patient was becoming more obtunded with a rising serum calcium (Figure), and further workup was interrupted on his fifth hospital day by the necessity to treat his hypercalcemia. He received approximately sixty mEq. PO_4 (as $K_2HPO_4 + KH_2PO_4$) intravenously over a twelve-hour period and during this procedure developed an antero-septal myocardial infarction. He convalesced with only mild congestive heart failure and became more alert after the lowering of serum calcium; but his pulmonary infection failed to clear and he developed progressive airway obstruction necessitating tracheostomy. An open biopsy of the cervical mass was obtained and revealed squamous cell carcinoma. He continued to deteriorate, developed elevated BUN and phosphorus terminally and expired on his thirty-fifth hospital day.

A squamous cell carcinoma of the distal esophagus was found at autopsy, with metastases to the thyroid, heart, adrenal, pleura, mediastinal lymph nodes, liver, and thoracic spine. Also noted were an antero-septal myocardial infarct, and a calcified granuloma of the right lung.

---

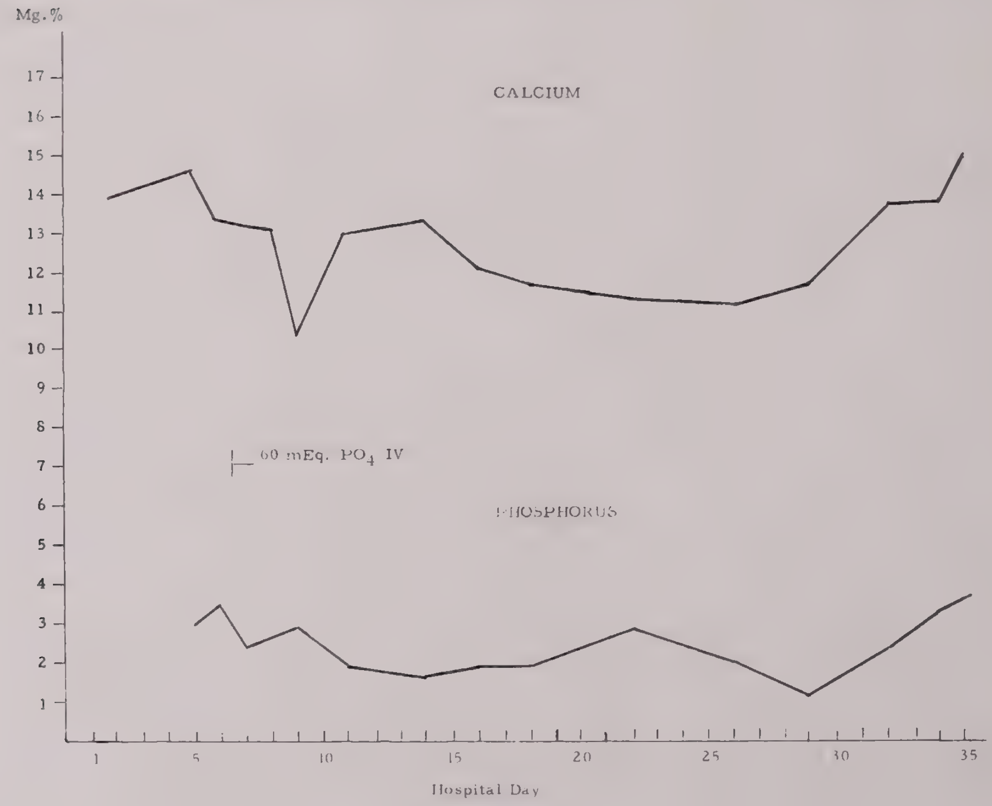
*Presented as a Medical Grand Rounds at Hennepin County General Hospital, March 18, 1969.

History

Hypercalcemia is a disorder that causes significant morbidity and may in some instances prove fatal. A number of disease states require consideration when a patient is found with an elevated serum calcium. Little enlargement has been made upon a summary credited to Albright in 1941[1]: Laboratory error, primary hyperparathyroidism, hyperthyroidism, immobilization (especially with Paget's disease or fractures), vitamin D intoxication, milk alkali syndrome, and neoplasm with skeletal lesions. Hypercalcemia associated with non-parathyroid neoplasm with no skeletal lesions has more recently been reported.

Gutman,[2] in 1936, described a man who had bronchogenic carcinoma with elevated serum calcium and low serum phosphate. He noted normal parathyroid glands and the absence of skeletal lesions at necropsy. In 1941, Albright[3] reported a similar case and was the first to postulate the production of parathyroid hormone by a non-parathyroid tumor. Connor, Howard and Thomas,[4] in 1956, reported two patients who reverted to normal calcium levels following removal of a lung tumor. Finally, in 1964, Tashjian et al.[5] identified a parathyroid hormone-like substance in six non-parathyroid tumors associated with hypercalcemia.

Hypercalcemia occurs with sufficient frequency to be considered in any patient with known cancer. Woodward[6] reported that 9% of 699 patients having a variety of malignancies and skeletal metastases exhibited hypercalcemia at some point during their disease. Metastatic bone disease or myeloma and non-metastatic malignant tumors accounted for 55% and 15% respectively of all elevated serum calcium determinations found at the University Hos-



Figure

pitals of Cleveland from 1961 to 1965.[7] Carey[8] studied 100 consecutive male patients with the tissue diagnosis of bronchogenic carcinoma. Eight were noted to have serum calcium greater than 12. Six had no clinical evidence for bone metastases and negative bone survey roentgenograms. All had "normal parathyroid glands" at post-mortem examination, and no other cause of hypercalcemia was found. While malignancy with skeletal metastases is known to have a high incidence of hypercalcemia, of patients with known cancer and hypercalcemia, 14-20% will have no demonstrable skeletal lesion.[9]

Etiology

No single explanation for these observations is possible. Osteolytic lesions in bone are felt to mobilize calcium at a rate faster than it can be excreted by the kidneys; but this cannot explain the hypercalcemia sometimes occurring with osteoblastic lesions. An early postulation was elaboration by the tumor of a calcium-binding substance, i.e., a globulin or lipoprotein similar to that found in hens with "normal" hypercalcemia during egg laying. Such a substance has not been found; and in patients studied, elevated serum calcium is found to be diffusable and normally ionized.[10]

Parathyroid Hormone

The presence of hypercalcemia, hypophosphatemia and elevated alkaline phosphatase strongly suggests the possibility of excess parathyroid hormone, presumably caused by excess stimulation of endogenous parathyroid hormone production or excess tumor production of parathyroid hormone (or parathyroid hormone-like substance). Sporadic cases appear with hyperplasia of parathyroid glands in association with hypercalcemia and malignancy; however, no known trophic hormone has ever been demonstrated in parathyroid regulation. Ionized serum calcium is accepted as the agent active in negative feedback in parathyroid hormone regulation.

As previously mentioned, Tashjian, Levin and Munsen,[5] using a very sensitive quantitative complement fixation reaction, have detected an antigen reacting with anti-parathyroid hormone in six tumors from patients with the hypercalcemia syndrome. The tumors originated from kidney, lung, pancreas, and colon without evidence of bone lesions. Extracts of non-tumor tissue from the same patients and similar tumors from patients without hypercalcemia were serologically negative. This assay method is several hundred times more sensitive than the previously used bio-assay and, in fact, detected an increase in circulating parathyroid hormone in one patient. Extracts from three of these tumors produced a small rise in serum calcium in parathyroidectomized rats. The evidence, therefore, seems irrefutable that at least some tumors are capable of secreting excess parathyroid hormone (or parathyroid-like hormone). Hypernephroma and bronchogenic carcinoma have accounted for approximately 60% of the reported cases in this category, so that they are by no means confined to an entodermal origin.

Vitamin D

Parathyroid hormone secretion will not explain all such cases of hypercalcemia, as immunoassay has been negative on numerous occasions. Localized carcinoma of the breast is strikingly absent from series with detectable parathyroid hormone. Gordon[11] et al. reported 20 of 80 cases of carcinoma of the breast to have hypercalcemia with normal bone surveys. These cases had hyperphosphatemia and normal renal tubular reabsorption of phosphate. This, together with the frequent response to cortisone, led Gordon to postulate the secretion of a vitamin D-like substance rather than parathyroid hormone. He subsequently was able to detect an osteolytic sterol in eleven of twelve breast cancers removed at surgery. This substance significantly increased urinary calcium in parathyroidectomized rats and was identified by thin-layer chromatography to be very closely related to 7-dehydrocholesterol (provitamin D_3). The osteolytic activity of this sterol probably accounts for the rise in serum calcium in carcinoma of the breast. These twelve patients had normal serum calcium determinations, suggesting that the body's efficient homeostatic mechanisms prevented hypercalcemia.

Conclusion

Elevated serum calcium, sometimes to life-threatening proportions, may coexist with malignant disease. While usually secondary to skeletal metastasis, it may occur with localized disease by production of a parathyroid hormone-like substance, a vitamin D-like substance, or by yet unidentified substances.

It's the Law

Misfilling of Prescription for "The Pill"

The patient had been given a prescription for Norinyl, an oral birth control pill, by her physician. The prescription was mistakenly filled with Nardil, a mild tranquilizer. The patient took the pills furnished and in due time gave birth to a normal healthy boy.

The patient and her husband sought to recover as damages the cost of confinement, the patient's loss of earnings and support of the child until he was 21.

The court ruled that damages could not be awarded for the result of a natural conjugal act of husband and wife. The court ruled that any public policy that may exist favoring planned parenthood is outweighed by the public policy requiring the responsibility of parenthood to be borne by the parents.

Laboratory Letter

"Normal Ranges" and Aging

> *"And so from hour to hour we ripe and ripe,*
> *And then from hour to hour we rot and rot,*
> *And thereby hangs a tale."*
>
> William Shakespeare, As You Like It, II, vii

To begin a letter about a scientific matter with a quote from Shakespeare may strike you as unorthodox. Perhaps so. But Shakespeare clearly saw what most "normal range" finders seem to have forgotten: as we age, we change. Before puberty, our metabolism and our body mature. Later, our hair grays, our vision dims, our skin wrinkles, and our walk slows. Or, if you want to be scientific, cardiac output and conduction velocity fall, renal plasma flow and glomerular filtration rate drop off, and vital capacity and basal metabolism rate gently, but relentlessly, decrease.

Why then shouldn't "normal ranges," which indirectly measure metabolism and body composition, change? We believe they do. Many ranges shift with age, depending partly on the sex of the subject tested; and clinicians who blindly accept a fixed normal range and disregard the patient's age and sex are going to make mistakes.

As far back as 1938, Rockefeller Institute investigators showed that BUNs climb in "healthy men"[1]; Keyes and his group at the University of Minnesota demonstrated in 1950 that cholesterol ranges fluctuate in men and women[2]; a couple of Cincinnati workers disclosed that calcium levels drift down with age[3]; and, just last year, a group at the University of Missouri used a computer to show that "normal ranges" for many tests shift with advancing age.[4]

All of which supports a recent study of our own. We took data from 6300 chemistry graphs (done on the Sequential Multiple Analyzer 12/30), punched the numbers on IBM cards, and ran the cards through a computer. The computer displayed frequency distribution patterns for the 12 tests for each age and sex for each decade. And then, instructed by a program that we will describe in detail in a later paper, we calculated the probable "normal range" for each group of patients. We list below those tests in which age and sex seemed to make a difference. You may find this data useful, as we have, in interpreting chemistry graphs.

Age	Cholesterol	Calcium	In. Phos.	Albumin	T. Protein	Uric Acid	BUN	Glucose
20-29M	110-215	8.8-10.7	2.3-5.1	3.1-4.7	6.1-7.8	3.2-8.5	7-18	70-115

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

EDUCATION PLUS: What midwestern high school of 170 boys currently has alumni at Harvard, Princeton, Swarthmore, M.I.T., McGill, London and Oxford (Rhodes Scholar), welcomes Americans, and produces great hockey teams? St. Johns-Ravenscourt School, Winnipeg 19, Manitoba. Headmaster: H. John P. Schaffter, M.A. (Cambridge), 204-453-3016.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

IMMEDIATE OPENING: Internist or General Practitioner to join six man multispecialty group in northeastern Wisconsin. Excellent professional opportunity to practice in a friendly community, only two actively practicing physicians (General Practitioners) in the community outside of our clinic. Salary commensurate with training and experience first year and then full partnership. Ideal, safe small city living for the family on scenic Lake Michigan with excellent fishing, boating and hunting. All this and still only 1½ hours drive to Milwaukee or 45 minutes to Green Bay or lovely Door County. For complete details contact Robert E. Myers, M.D., Garfield at 23rd, Two Rivers, Wisconsin 54241.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

THE ADOLF GUNDERSEN MEDICAL FOUNDATION of La Crosse, Wisconsin, announces the establishment of a fully accredited three-year residency training program in Internal Medicine at Lutheran Hospital, La Crosse, Wisconsin. The hospital staff consists of a 65-man multiple specialty group with offices in a connecting modern clinic building. Eighteen fully qualified Internists serve as a nucleus of the teaching program. All staff men are full-time and salaried. This clinic-hospital complex serves as a referral center for a 100-mile radius. The hospital has a 375-bed facility. An intensive in-house training program is supported by weekly guest consultants. Stipend: $600 to $700 per month, plus housing and miscellaneous. Located in a progressive community with expanding university and private college. Population 50,000. Excellent school and recreation facilities. Applications being considered at all levels. Write: Edwin L. Overholt, M.D., Director, Medical Education and Research, Gundersen Clinic, Ltd., 1836 South Avenue, La Crosse, Wisconsin 54601.

AVAILABLE — TROUT STEAM FRONTAGE, on Cascade River, also forest and meadow cabin sites, N. Shore, in Forest, 2 mi. to Pike Lake boat launch area, 3 mi. to Lake Superior, 10 mi. to town, Cook Cty. Airport, N. of town. Long term lease. E. Harvey, Grand Marais, Minn. 55604 .

RADIOLOGY RESIDENCY POSITION OPEN: AMA and American College of Radiology approved program in 500-bed general hospital. Diagnosis, cardiovascular special studies, therapy, and isotopes. Write: Dept. of Radiology, Swedish Hospital, 900 South 8th Street, Minneapolis, Minnesota 55404.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

EXCELLENT OPPORTUNITY for General Practitioner and General Surgeon to join 5 man general practice group. Services of Radiologist immediately available. Salary open. Liberal fringes with opportunity for early partnership. College town serving population of 22,000, 30 miles from Minneapolis-St. Paul. Contact Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin, phone number 425-5322.

GENERAL PRACTITIONER urgently needed to join busy, well established practice in North Central Minnesota community; excellent year round recreation area, best hunting and fishing in the State. Salary negotiable for the first year, early partnership if desired. Hospital owns and maintains clinic. Call me collect. A. H. Roth, M.D., Deer River, Minnesota, office number 246-8275 or home number 246-8164.

symptoms of mixed anxiety-depression are rarely clear-cut...

but they are often a clear indication for

Mellaril®

(thioridazine)

25 mg. t.i.d.

effective in mixed anxiety-depression and in moderate to severe anxiety

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

SANDOZ PHARMACEUTICALS, HANOVER, N.J. SANDOZ 69-384

Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic / antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other
depressants. As with all CNS-acting drugs,
tion patients against hazardous occupatior
quiring complete mental alertness (*e.g.*, oper
machinery, driving). Though physical and
chological dependence have rarely been rep
on recommended doses, use caution ir
ministering Librium (chlordiazepoxide h
chloride) to known addiction-prone indivi
or those who might increase dosage; withd
symptoms (including convulsions), follc
discontinuation of the drug and similar to

Though generally not recommended, if
nation therapy with other psychotropics
indicated, carefully consider individual
acologic effects, particularly in use of po-
ing drugs such as MAO inhibitors and
thiazines. Observe usual precautions in
ice of impaired renal or hepatic function.
oxical reactions (*e.g.*, excitement, stimula-
nd acute rage) have been reported in psy-
c patients. Employ usual precautions in
ent of anxiety states with evidence of im-
g depression; suicidal tendencies may be
t and protective measures necessary. Vari-
ffects on blood coagulation have been
ed very rarely in patients receiving the
and oral anticoagulants; causal relation-
as not been established clinically.
VERSE REACTIONS: No side effects or
stations not seen with either compound
have been reported with Librax. When
iazepoxide hydrochloride is used alone,
ness, ataxia and confusion may occur,
lly in the elderly and debilitated. These
are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

ROCHE
ROCHE
LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol. An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take. PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Clinical Review

Tumors in Infancy and Childhood*

Advances in the diagnosis and treatment of tumors in infancy and childhood have been many during the past decade. In this review, some basic aspects of tumors in infancy and childhood will be considered, but detailed characteristics of individual tumors will not be discussed. The purpose is to promote overall knowledge and understanding of childhood tumors and aid in meeting the challenge that now confronts all those working in the field of pediatrics.

Cancer kills more infants and children than does almost any other disease, including tuberculosis, heart disease, and poliomyelitis.[1] It is fourth in causes of death in the preschool years and second in the age group five through 14 years, being exceeded in the latter group only by accidents.[1] Some of the most rapidly fatal cancers, such as acute leukemia, occur in infants, and some of the most disfiguring tumors occur in children. In 1956, almost 4,000 infants and children in the United States died from cancer, representing 9% of all deaths in that age group.[1] In a recent survey, more than 1% of all patients entering a children's hospital had malignant tumors.[2]

The first authentic account of tumors in children was that of Wardrop in 1809, who mentioned 20 malignant tumors of the eye in children. In 1846, Walshe reported a tumor of the dura mater in a child; he also collected reports of 44 cancers of the cerebral meninges and cranium.

The first comprehensive survey of the literature on childhood cancer was that of Duzan, who found 231 cancers reported between 1832 and 1875. A few years later, Picot reported an additional 242 cancers in children. This was followed by a review by d'Espine and Picot in 1900, giving a total of 640 childhood cancers.

Until the 1930s, reports continued to be sporadic. Significant contributions were those of Steffen (1905), Williams (1908), Wright (1910), Warthin (1915), Schultze (1926), Raymond (1929), and Helmholz (1931).

After 1930 the number and scope of clinical and experimental reports on the various aspects of cancer in children increased rapidly. Today there is a vast literature in a great variety of medical journals.[3]

General Appraisal

Childhood cancer is most often observed in the first five years of life, probably reflecting the embryonal nature of certain of the more common tumors encountered in this period. They may be present at birth or may arise postnatally from cells that have not attained complete maturation. The comprehensive review of congenital malignant neoplasms by Wells[4] in 1940 remains the classic to that date. Vinik and Altman[5] in 1966 reported congenital fibrosarcoma, neuroblastoma, reticulum cell sarcoma, undifferentiated sarcoma, and malignant histiocytosis. Congenital cancers may affect the kidneys, eyes, adrenals, testes, ovaries, and many other soft tissues. Rudimentary organs are also common sites.

A pregnant woman with far-advanced neoplastic disease, especially malignant melanoma, may transmit the process to her offspring.[6] Reports indicate that infants have died of a malignant tumor similar to that of the mother.[7] Cyst, angioma, mole, and chorioepithelioma are the commonest types of fetal tumor.[3]

Sites of origin of tumors in children differ from those of adults. Common epithelial tumors in adults (carcinoma of the skin, stomach, breast, and uterus) are rare in early life. The six body sites most often involved in the child are the intracranial cavity, eyes and orbit, bones, hematopoietic sites, soft somatic tissues, and retroperitoneal region.

The terms "malignant" and "benign" as applied to tumors may be misleading. Because of their location, histologically benign tumors of the central nervous system are associated with high mortality rates. Wilms's tumor and even neuroblastomas are often initially encapsulated.

---

*See editorial page 1629.

Benign Tumors

These are far more common in early life than are malignant ones, and many of them represent hamartomas rather than true neoplasms. Hamartomas are tumor-like, non-neoplastic malformations characterized by localized overgrowth of one or more tissues indigenous to the site in which they arise, for example, angiomas. Benign tumors found in adults, such as uterine polyps and fibroids, adenomas of the thyroid and adrenal glands, adenomatous hyperplasia of the prostate, fibroadenomas of the breast, and papillomas of the urinary bladder are rare in early life.

In a series of 1,872 benign tumors in children, those of mesodermal origin far outnumbered those of any other origin; 1,525 (81.5%) were of mesodermal origin (vascular 769, soft parts 563, bone 193), 59 ectodermal, 15 endodermal, six mixed, and 267 of miscellaneous origin.[3]

Malignant Tumors

Sarcoma is far more common than carcinoma in children. The reverse is true in adults. The location and the histologic type of malignant lesions have varied with the years and from clinic to clinic. Of 1,418 malignant tumors reported by Dargeon,[3] 534 (37.7%) were lymphomas and leukemias, 383 (27%) sarcomas (osseous and somatic), 105 (7.4%) carcinomas, and 396 (27.9%) others (171 neuroblastomas, 93 Wilms's tumors, 57 retinoblastomas, 14 central nervous system tumors, and 61 miscellaneous tumors).

Handy and Goldberg[8] reported that malignant neoplastic conditions in patients less than 15 years old occur in decreasing order of frequency as follows: leukemias, brain tumors, renal and adrenal tumors, lymphosarcomas, tumors of the digestive system, sarcomas of soft tissue, and bone tumors.

Of 2,230 autopsy protocols of children less than 15 years old seen at the Mayo Clinic for the 16-year period 1950 through 1965, 204 concerned patients with malignant tumors, distributed as follows: lymphomas and leukemias 97, (leukemias 83, lymphomas 14), intracranial tumors 66, sarcomas 17, renal and adrenal tumors 11, and miscellaneous tumors 13.

Leukemia

Leukemia, a fatal disease in children, is characterized by uncontrolled proliferation of leukocytes and their precursors. It is usually acute and of relatively short duration in children. It occurs more often in the first five years of life, with a second peak at eight to nine years. The type of cells predominantly involved in leukemia offers a basis for classification. In childhood, however, the predominating cell is often so undifferentiated morphologically (stem cell) that a specific diagnosis according to origin of the cell cannot be made.

The symptoms of leukemia are due to (1) hypermetabolism associated with rapid growth and destruction of leukemic tissue, (2) bone marrow dysfunction, and (3) disturbances of organs involved in leukemic proliferation. The spleen, liver, and kidneys are usually enlarged. Enlargement of lymph nodes is generally not marked, but mediastinal and abdominal nodes may be extensively enlarged.

Chronic leukemia is uncommon in children. It is almost always myelocytic in origin, and usually has its onset after the age of eight years. Congenital leukemia, present at birth or developing shortly thereafter, is always of the acute type.

Tumors of the Head and Neck

Various tumors may occur in the head and neck of children. Of 233 such tumors reported by Dargeon,[3] 68 were of the eye and orbit (56 retinoblastomas), 59 of the soft parts (21 neuroblastomas, 12 rhabdomyosarcomas), 25 of the nasopharynx, 19 of the thyroid, 11 of the tonsil, 10 of the skin, 10 of the brain and membranes, seven of the skull, six of the nasal cavity, four of the paranasal sinuses, two of the salivary glands, two of the palate, three of the mastoid and ear, six of the lip, gingiva, and cheek, and one rhabdomyosarcoma of the tongue.

Eye

Retinoblastoma is the most common tumor of the eye. It has a marked hereditary proclivity and may be present at birth, but the average age at discovery is about two years. Both eyes are involved in one third of the patients afflicted. In advanced cases the tumor produces a white reflex in the pupil and may break through the globe and extend to the surrounding structures. Reese[9] states that more than half the offspring of a parent who survives the disease develop retinoblastoma. Healthy parents who have one child with retinoblastoma only rarely have a second afflicted child, and such parents should not be discouraged from having more children.

Most tumors of the orbital tissue are mesenchymal in origin. Proptosis is usually an early symptom.

Nasopharynx

Angiomas and polyps often occur in the nasopharynx. Juvenile nasopharyngeal angiofibroma occurs almost entirely in males, generally between ages 10 and 20 years. Nasal obstruction and epistaxis are the usual clinical manifestations.

Teratomas may arise at the base of the skull, in the roof of the pharynx, or in the palate, and may project into the mouth, nose, or cranial cavity. A chordoma of the base of the skull may project into the nasopharynx or manifest itself initially as an intracranial tumor.

Tumors of the salivary glands are uncommon, but chiefly affect the parotid. Hemangioma is the most common salivary tumor in early life, and mucoepidermoid carcinoma is the most common malignant salivary tumor in children.

Tumors of the larynx are rare. Possible obstruction of the airway by these lesions may cause a critical situation. Angiomas, polyps, and fibromas may occur in the larynx.

The Neck

Teratomas, lymphangiomas, lymphomas, neuroblastomas, and rhabdomyosarcomas occur in the neck. A thyroglossal duct cyst in the midline, a branchial cleft cyst along the lateral aspect of the neck, and an aberrant salivary, thyroid, parathyroid, or thymic tissue may present as a mass in the neck.

Thyroid

Benign tumors of the thyroid are rare. Thyroid carcinoma may be present at birth; the average age at occurrence is about nine years. Approximately 65% occur in girls.[10] Papillary carcinoma accounts for the largest number. An asymptomatic nodule in one lobe of the thyroid is the classic clinical feature. The incidence of cervical metastasis when these patients are first seen has been reported to be as high as 70%.[11] The lungs are the most common distant site for metastasis. Every thyroid nodule identified in a child should be removed and examined, since the incidence of carcinoma is about 70%.[6] In 1961, Winship and Rosvoll[12] reported that 38% of 562 recorded thyroid carcinomas in children were associated with a history of previous therapeutic irradiation of the neck.

Adenomas of the parathyroid glands, which may be aberrant in the region from the mandible to the mediastinum, are rare in children.

Tumors of the Brain and Spinal Cord

These tumors are rare in infancy, but the incidence increases rapidly to a peak at five to six years of age. There is no general predilection for race or sex. Sixty to 70% of brain tumors in children are beneath the tentorium cerebri,[6] the reverse of the pattern in the adult. Of the supratentorial tumors, more than half are in the midline. About 75% of intracranial tumors in childhood are gliomas, of which two thirds are astrocytomas and medulloblastomas. Ependymomas, brain-stem gliomas, and gliomas of the hemispheres constitute an additional 15%, and the remainder are craniopharyngiomas, meningiomas, sarcomas, pituitary adenomas, hamartomas, hemangiomas, and dermoids. The acoustic neuroma, meningioma, and pituitary adenoma of adult life are rare, as are metastases from non-cerebral neoplasms.

Of 1,369 reported intracranial tumors of infancy and childhood,[3] 369 were astrocytomas, 283 medulloblastomas, 143 ependymomas, 81 craniopharyngiomas, and 493 miscellaneous tumors.

The general symptoms of brain tumor in childhood are caused by increased intracranial pressure. Vomiting usually occurs in the morning, often without nausea; only late in the course does projectile vomiting appear. Headache occurs in 70% of cases, more frequent at night or when the child arises from sleep. Enlargement of the head occurs most often in children less than four years old. Convulsions, mental change, gait disturbance, and diplopia are other symptoms.

Tumors of the spinal cord rarely occur in children. They affect the sexes equally. Ependymomas are the most common type. Austin[13] reported 30 spinal cord tumors in children in a series of 409 spinal cord tumors representing all ages and seen over a period of 25 years in a neurologic clinic.

Tumors of the Thorax

Tumors of the breast and of the chest wall, benign or malignant, are uncommon in children,[1,14,15] but malignant ones are more common than benign ones. Sarcomas make up the principal group of these tumors.[11,16,17]

Lung

Pulmonary metastasis from Wilms's tumor, neuroblastoma (rare), or osteogenic sarcoma is more common than primary malignancy of the lung. There have been some rare reports of various types of sarcoma and epithelial malignant tumors of the lung.[18-20] Bronchial adenoma is occasionally seen, and Ward, Bradshaw, and Prince[21] in 1954 found reports of eight cases in children and added a ninth.

Heart

Tumors of the heart are rare. Rhabdomyomas show a definite predilection for infants and children. Myxomas are the most common primary tumors of the heart, and sarcomas the second.[1]

Mediastinum

Cysts and tumors of the mediastinum are not rare. The clinical manifestations of these masses are essentially those of expanding, space-occupying lesions and reflect their location. Symptoms most often encountered are chest pain, cough, respiratory distress, hemoptysis, dyspnea, and weight loss. A number of these cysts and tumors, even when large, are asymptomatic and show only incidentally on chest roentgenograms. The distribution of various types of mediastinal cysts and neoplasms seen in a combined series from the Mayo Clinic (56 cases)[22,23] and the Johns Hopkins Hospital (25 cases)[24] is as follows: neurogenic tumors 37%, teratomatous tumors 25%, cysts of foregut origin 16%, hemangiomas 6%, cystic hygromas 5%, anaplastic neoplasms 5%, miscellaneous tumors 6%. The neurogenic tumors, occurring entirely in the posterior mediastinum, make up the largest group, and the teratomas and dermoids in the anterior mediastinum the second largest.

The tumors and cysts occurring in the different parts of the mediastinum and listed in descending order of frequency are as follows: (1) superior mediastinum: goiter, bronchogenic cyst, parathyroid adenoma, myxoma, lymphoma, and neurilemmoma; (2) anterior mediastinum: thymoma, teratoma, goiter, parathyroid adenoma, lymphoma, lipoma, fibroma, angioma, chondroma, thymic cyst, and rhabdomyosarcoma; (3) middle mediastinum: bronchogenic cyst, lymphoma, and pericardial cyst; and (4) posterior mediastinum: ganglioneuroma, neuroblastoma, neurilemmoma, neurofibroma, neurofibrosarcoma, ganglioneuroblastoma, lymphoma, gastroenteric cyst, chondroma, myxoma, goiter, fibrosarcoma, and meningocele.

Since some mediastinal tumors have malignant potentialities, and most others sooner or later cause symptoms by virtue of their location, all such cysts or tumors should be removed when discovered even if they have not yet produced symptoms.

Abdominal Tumors

The discovery of an abdominal mass in a child presents a challenging problem. More than half of these masses are nonsurgical; the remainder (40 to 45%) are of surgical importance. Hydronephrosis accounts for a little more than half of the surgical conditions. The remainder are neoplastic and must be considered malignant until proved otherwise.

In a series of 653 palpable abdominal masses in infants and children,[25] 372 (57%) represented medical conditions and 281 (43%) represented surgical conditions. The medical conditions were leukemia (209 cases), hepatosplenomegaly of unknown etiology (67 cases), Banti's syndrome and splenomegaly (49 cases), Hodgkin's disease (15 cases), and miscellaneous (32 cases). The surgical conditions were of genitourinary (49.5%) or of nongenitourinary (50.5%) origin. Genitourinary conditions were hydronephrosis (40.2%), Wilms's tumor (30.2%), cystic disease of the kidney (22.3%), and miscellaneous conditions (7.2%). The nongenitourinary conditions were intraperitoneal lesions (40.1%), neuroblastomas

(33.8%), primary retroperitoneal tumors (lymphoma, sarcoma) (20.4%), and miscellaneous conditions (5.6%).

Faced with an abdominal mass, one must first determine whether it is intraperitoneal or retroperitoneal. Shifting of the intraperitoneal mass can be felt and seen as it is pushed or as the patient is moved into different positions. Retroperitoneal masses, on the other hand, are fixed and are felt deep in the renal fossa. Malignant masses are hard; a hydronephrotic mass is usually soft. Appropriate roentgenographic examinations are essential to assess the nature and extent of the lesion.

About nine tenths of the retroperitoneal neoplasms are Wilms's tumors or neuroblastomas. Teratoma is the third most common type.[6]

Wilms's Tumor

Almost all renal tumors in infants and children are Wilms's tumor.[26-28] More than 90% of these tumors appear before the sixth year of life, the average age being three years. The tumor is bilateral in 4%, on the right in 44%, and on the left in 52%.[29,30] The sexes are almost equally affected, and familial occurrence is rare.[31-36] The primary clinical manifestation is an abdominal mass, present on physical examination in 90% and reported by the parents in 64%. It is careful examination by the physician that detects many of these tumors. Pain occurs in about 26% of cases, fever in 20%, vomiting in 16%, constipation in 6%, and diarrhea in 3%; hypertension may be encountered.[31,37,38] Metastatic lesions are present in 20 to 50% of patients on initial diagnosis and appear most commonly in the lung, then in the liver, and rarely in bone. Hematuria develops in 15 to 20% and is a grave prognostic sign. The presence and normality of the opposite kidney should be established by pyelography.

Management of patients with Wilms's tumor is still not standardized. It is universally agreed, however, that the best hope for permanent cure rests on excision of the tumor. Irradiation as the sole therapy gives poor results. The controversy hinges on the use of irradiation to augment surgical treatment. Recently dactinomycin (actinomycin D) has been reported as having had beneficial effects when given both preoperatively and postoperatively. Prognosis for the youngest children is much better than for older ones.[39,40]

Neuroblastoma

Although this tumor may originate anywhere along the sympathetic chain, 70% of neuroblastomas arise from the adrenal or upper abdominal sympathetic ganglia. It is the most common malignant neoplasm to be identified at birth, when metastatic lesions may already be present. There is no predilection for either sex or any race. Two thirds of these tumors originate on the left side[41] and 40% appear within the first year.[42] The peak incidence of admissions to the hospital is about age 1½ years. The presenting complaint is usually that of an abdominal mass. Pain, fever, anorexia, vomiting, weakness, and failure to gain weight —each or all may occur. A characteristic roentgenographic finding is calcification in the soft-tissue tumor. Pulmonary metastasis occurs in about 12% of cases and osseous metastasis in 35%.[43] Treatment is primarily surgical. The younger the child at the time of diagnosis the better the prognosis.

Tumors of the pancreas are extremely rare. Up to 1959, nine cases of adenocarcinoma of the pancreas had been reported.[44,45]

Metastatic neoplasms of the liver are more common than primary tumors in childhood. Most primary neoplasms are malignant.[6] These tumors must be considered in the differential diagnosis of a mass in the upper part of the abdomen. Up to 1958, 100 primary hepatic tumors in children had been reported.[46] In the newborn, hemangioendothelioma, solitary cyst, and cavernous hemangioma are the most common. Between birth and the age of two years, almost any benign or malignant tumor may occur in the liver. Beyond the age of two years, carcinoma, mesenchymoma, and solitary cyst are fairly common.[47]

Gastrointestinal Tract

Tumors of the gastrointestinal[48-56] tract may be asymptomatic or may be manifested by abdominal pain, intestinal obstruction (especially intussusception), hemorrhage, or rarely a palpable abdominal mass. Except for juvenile polyps, no tumor of the gastrointestinal tract can be considered common in children, but both benign and malignant neoplasms do occur.

Juvenile polyps have their peak incidence around four years of age. They are usually solitary and located in the rectum. There is no evidence that these polyps undergo malignant transformation.

Multiple familial polyposis is characterized by the presence of innumerable sessile and pedunculated tumors in the rectum and colon. If untreated, almost all patients with such tumors develop carcinoma. Treatment consists of total colectomy.

The polyps in Peutz-Jeghers syndrome are usually multiple and are located at several sites in the gastrointestinal tract, the small intestine being the site of predilection. The lesions are usually benign.

The polyps in multiple polyposis of the colon and rectum in Gardner's syndrome, which may not develop until adult life, are scattered and do not carpet the colonic mucosa. They have a striking tendency to malignant transformation.

Lymphoma is the most common malignant neoplasm of the gastrointestinal tract encountered in early life. The peak incidence is at three to eight years of age. Although usually arising in the small intestine, lymphomas may originate in the colon or even the stomach.

Carcinoma of the colon is rare in children. It may occur as a complication of multiple familial polyposis or of chronic ulcerative colitis. Rarely does it occur in the absence of known predisposing factors.

Carcinoid is seen in less than 0.2% of the appendices removed from children less than 14 years old.

Hemangioma of the intestine, teratoma of the stomach, and leiomyoma and leiomyosarcoma of the gastrointestinal tract are extremely rare.

Tumors of Bone

Various benign and malignant neoplasms of bone[57-71] have been described in children. Pain is common to most bone tumors that occur in children. Detecting local swelling and tenderness is important, but the roentgenographic appearance, although not pathognomonic, is more helpful in detecting the nature of the tumor. In a given patient the most accurate diagnosis is usually made by considering all aspects of the lesion: clinical history and signs, roentgenographic appearance, and especially pathologic findings. A roentgenographic survey of the other bones is necessary to determine whether the lesion in question is single or multiple.

Ewing's Tumor

The most common primary malignant tumors of bone are osteogenic sarcoma and Ewing's tumor, the majority of which occur between ages 10 and 25 years. Males are affected more often than females. Osteogenic sarcoma characteristically involves the metaphyseal end of a long bone, whereas Ewing's tumor involves the shaft. Osteogenic sarcoma is more common than Ewing's tumor.

Osteochondroma

Solitary osteochondroma is one of the most common of the benign osseous tumors. Bone cysts occur almost exclusively in the child and seldom develop after closure of epiphyses.

Lymphoma and leukemia frequently affect the osseous system in children. Lesions that may simulate plasma cell myeloma roentgenographically in the child are most likely due to reticuloendotheliosis.

Tumors in the skeleton may be metastatic from primary neoplasms known to occur in the child (neuroblastoma, Wilms's tumor, and retinoblastoma). Hence, the presence of such a skeletal tumor should lead one to search for the primary neoplasm.

Soft-Tissue Sarcomas of Infants and Children

Here the clinicopathologic studies[1,3,6,9,72-91] made by one of us (G.H.M.) will be summarized.

Material and Method

The soft-tissue sarcomas reported here occurred in 135 patients less than 16 years old who were seen at the Mayo Clinic in the 16-year period 1950 through 1965. The clinical records and autopsy protocols were reviewed and follow-up data on all survivors were obtained. Tissue sections were available for review in all cases. Tumors of the central nervous system, intracranial sarcomas, and malignant lymphomas are not included in the series.

Observations

Of the 135 patients, 67 were boys and 68 were girls. The mean age was 7.3 years. Ninety-two patients have died, 36 are living, and seven are lost to follow-up.

Eighty-one of the 135 patients received their initial treatment prior to January 1, 1961. Nineteen or 20.9% of these 81 patients are living five or more years after diagnosis.

Of the 11 histologic types of sarcoma encountered, rhabdomyosarcoma was the most common (75 cases), followed by sarcoma of undetermined histogenesis (27 cases), malignant synovioma (10 cases), juvenile fibrosarcoma (six cases), neurofibrosarcoma associated with von Recklinghausen's disease (five cases), leiomyosarcoma (three cases), malignant hemangiopericytoma (three cases), liposarcoma (two cases), dermatofibrosarcoma protuberans (two cases), malignant mixed mesenchymoma (one case), and extraosseous osteogenic sarcoma (one case).

The most common site of primary lesions was head and neck (51 cases), followed by the pelvis (28 cases), lower extremity (23 cases), upper extremity (18 cases), trunk (10 cases), and retroperitoneum (five cases).

The rhabdomyosarcomas were classified as embryonal (61 cases), embryonal with botryoid pattern (11 cases), embryonal with alveolar pattern (two cases), and pleomorphic (one case). The most common site of the primary tumor was the head and neck (38 cases); other sites were the pelvis (22 cases), extremities (nine cases), retroperitoneum (five cases), and chest wall (one case). Of the 75 patients, 60 have died and 15 are living. As of 1966, nine patients have lived five years or more and apparently are free of disease, four are living and free of disease after periods ranging from two months to three and a half years, and two are alive but have uncontrolled metastasis. Of the 51 traced patients treated prior to January 1961, seven (14%) lived five or more years after their initial treatment.

When practicable, ablative surgery appears to be the most effective treatment for rhabdomyosarcoma. When such treatment is not feasible, irradiation combined with chemotherapy and as wide a surgical removal as possible seems to be the best alternative for control of the primary lesion. The chemotherapeutic agent most frequently used in this series was dactinomycin.

General Clinical Aspects of Tumors in Childhood

The value of a complete history and a thorough physical examination in pediatrics is nowhere greater than in establishing the diagnosis of childhood tumors. The possibility of cancer must be included in the differential diagnosis of many children's diseases. The clinical manifestations of certain neoplasms in infants and children may be those of an acute infectious process with a few or none of the classic signs of malignancy encountered in adults. The child who shows significant differences, physically or mentally, from his fellows may have cancer. Any undiagnosed disorder of short or long duration could be due to cancer. Except for leukemia and tumors of the central nervous system, most malignant neoplasms in infants or children are manifested as an abnormal mass, which may quickly enlarge.

The first requisite of diagnosis is teamwork involving the clinician, the roentgenologist, the surgeon, and the pathologist. Every solid mass in an infant or a child should be regarded as a malignant neoplasm until proven otherwise.

Management

Needless palpation of a suspected neoplasm should be avoided. The mass should be removed as soon as consistent with adequate clinical evaluation and preparation for operation. Thus, there should be minimal delay, minimal handling, and a minimal number of studies. The word "malignant" does not always indicate a hopeless disease. Patients with certain neoplasms, notably neuroblastoma and Wilms's tumor, can sometimes be cured even in the presence of recognizable metastasis.

From a biologic as well as a sociologic standpoint, children are not simply "microadults." Their specific needs fully justify the establishment of special facilities for their care. The traditional therapeutic principle of treating the patient (and the family) as well as the disease also finds wide application in the treatment of tumors in children.

The cure of a cancer in a child is a particularly significant triumph, when one considers the long-term salvage. In the removal of tumors in childhood one thinks in terms of 70-year survival, rather than the five-year survival that is the mark of successful cancer therapy in adults. Observance of accepted principles should prevent a number of needless deaths from cancer in infants and children.

The Biopsy

1850-1900

Microscopic pathology received attention in the case of King Frederick III of Prussia, who died in 1888 of a throat cancer after ninety-nine days as emperor of Germany. He had developed a growth on the vocal cords following an attack of measles; removed by cauterization, it recurred within weeks. German physicians diagnosed it as cancer, but British laryngologist Morell Mackenzie sent particles of the growth to Virchow, who found no evidence of malignancy. Autopsy showed extensive carcinoma of the larynx with metastases to the lymph nodes of the neck. In answer to professional recrimination, Virchow defended his diagnosis on the ground that the tissue he had examined was healthy and that he could not be responsible for the selection of specimens sent to him.*

Rx **Tussionex**®
(Resin complexes of Hydrocodone and Phenyltoloxamine)

...it works
(usually
for 10 to 12
hours*)

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic—oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.

*DOSAGE: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

xiety is expected in the cardiovascular patient. ttle may even be desirable.

when anxiety is exaggerated . . . when it rferes with sleep . . . when it aggravates diovascular symptoms, your help may needed.

urally, you'll want to reassure the patient.

perhaps prescribe Equanil (meprobamate) adjunctive therapy. It helps relieve anxiety tension specifically, yet gently.

ost 15 years' use has shown that Equanil sually well tolerated as well as effective. e effects are generally limited to transient wsiness; serious, therapy-interrupting e effects are rare.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Wyeth Laboratories Philadelphia, Pa.

Equanil®

(meprobamate) Wyeth®

No place for beginners

Terramycin®
(oxytetracycline)

An infection of rapid onset requiring prompt attention. Teenage girl with chills, fever, abdominal pain, backache and nausea. Frequent and urgent urination with burning. On examination—tenderness over kidney. Blood count and urinalysis confirm the diagnosis: acute pyelonephritis. Treatment is initiated with Terramycin. Within a few days of follow-up therapy, the patient is markedly improved. The pretreatment urine culture shows a strain of *E. coli* highly susceptible to Terramycin.

Experience has shown that Terramycin offers special advantages in treating urinary tract infections when strains of causative bacteria are susceptible. Broad-spectrum coverage unaffected by penicillinase. Effective tissue levels to help reach foci of infection in renal parenchyma. High urine levels—excreted by kidney in *active* form.

With Terramycin, you have the assurance that comes with choosing an agent physicians have depended on for over 18 years. In difficult as well as routine cases, when tests reveal susceptible organisms, consider Terramycin. One of the world's most widely used broad-spectrums.

Contraindicated: In individuals hypersensitive to oxytetracycline.

Warnings: Reduce usual oral dosage and consider antibiotic serum level determinations in patients with impaired renal function.

Use of oxytetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. This effect occurs mostly during long-term use of the drug, but it has also been observed in usual short-treatment courses.

During treatment with tetracyclines, individuals susceptible to photodynamic reactions should avoid direct sunlight; if such reactions occur, discontinue therapy.

Note: With oxytetracycline, phototoxicity is unknown and photoallergy very rare.

Precautions: Use of broad-spectrum antibiotics occasionally may result in overgrowth of nonsusceptible organisms. Where such infections occur, discontinue oxytetracycline and institute specific therapy. Increased intracranial pressure in infants is a possibility. Symptoms disappear upon discontinuation of therapy.

Adverse Reactions: Nausea, diarrhea, glossitis, stomatitis, proctitis, vaginitis and dermatitis, as well as reactions of an allergic nature, may occur but are rare.

Supply:* Terramycin Capsules: oxytetracycline HCl, 250 mg. and 125 mg. Terramycin Syrup: calcium oxytetracycline, 125 mg. per 5 cc. Terramycin Pediatric Drops: calcium oxytetracycline, 100 mg. per cc.

*All potencies listed are in terms of the standard, oxytetracycline.

More detailed professional information available on request.

GENERAL PRACTITIONER wanted for association leading to partnership with five Family Physicians, an Internist and a Surgeon in a modern congenial clinic environment. Rotating call schedule, ample vacation and study time. Recent deaths of two very active physicians assure an immediate practice. Community of 18,000 with excellent facilities fifty miles from Rochester and the Twin Cities. Contact: Burton A. Orr, M.D., Faribault Clinic, Faribault, Minnesota. Phone 507-334-3921.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

TEN MAN MULTISPECIALTY group needs an orthopedist, ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

PSYCHIATRIC RESIDENCIES: We offer nothing but excellent psychiatric training in a stimulating, well organized program located in a culturally advantaged community. Approved psychiatric training. Traverse City State Hospital, Michigan Department of Mental Health. Three and five year programs. Salary, 3 year program: $10,669; $11,191; $12,131. 5 year program: $12,152; $14,031; $16,328. $21,944; $23,093. NIMH-GP stipends available. Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

CAPITAL GAIN suggests the opportunity that applies to favorably located land consisting of 40-55 acres fronting on a state highway minutes West of Minneapolis. Purchase information is available through: R. A. Ruud Company, P.O. Box 5823, Minneapolis, Minnesota 55419.

LOCUM TENENS: Cover general practice for two to three weeks January, 1970. Remuneration of $500/week plus use of new home on lake, car, snowmobile. All expenses. Write: Minnesota Medicine, 441, 375 Jackson, St. Paul 55101.

WANTED: General Practitioner to join Wisconsin practice 75 miles from the Twin Cities. Excellent JCAH hospital, extended-care facility, and office in resort area. $30,000 plus bonus first year. Partnership then available without investment. Write. Minnesota Medicine, 442, 375 Jackson, St. Paul 55101.

ASSOCIATE NEEDED to join 38 year old in General Practice 45 miles west of Minneapolis. Partner leaving mid-October. Medical clinic adjacent to 3 year accredited 27 bed hospital, both built in 1960. Terms negotiable. For further information contact A. J. Stifter, M.D., Winsted, Minnesota 612-485-2622 or 2230.

WANTED: General practitioners and interested specialists to meet the medical needs of a fast-growing suburban community of St. Paul. Local physicians cannot handle the requests for medical attention and will refer patients to new physicians practicing in the area. Have information on several office sites (some equipped) for sale or lease to assist in getting established. An all-modern, fully accredited hospital available. Open staff. A hospital consulting firm studying present and future needs for both hospital and professional facilities. An excellent opportunity that has to be very attractive financially. Write: MINNESOTA MEDICINE—443, 375 Jackson Street, St. Paul, Minn. 55101.

PRACTICE OPENING in busy, booming, Bloomington. Sports and culture opportunities; good schools, etc. Join three young G. P.'s rotating call—new ideas in medical care—Contact Richard K. Simmons, M.D., 8040 Penn Ave. So. 612-888-9211.

DOCTOR NEEDED in Int'l Falls, Minn. Excellent opportunity, partnership or private practice, medical office space available, new 65 bed hospital under construction. Excellent fishing, hunting and a winter wonderland. For details write or call collect: Medical Action Committee, Edwin M. Swanson, City Drug Store, Int'l Falls, Minn.

PHYSICIAN WANTED: G.P.—join young group of 4 GP's 4 day office week, high earnings, early partnership, immediate work load. Well equipped, newer clinic, fully accredited hospital, excellent practice conditions. Call collect 612-445-1305. Shakopee Medical Center. J. E. Ponterio, M.D., Shakopee, Minn.

Special Article

Splitting of the Atrial Sounds

DAVID GOLD, M.D.*
Minneapolis, Minnesota

THE ATRIAL SOUND (fourth heart sound, S4) is a low-pitched, low-intensity sound usually best heard at the cardiac apex with the patient in the left lateral decubitus position. Usually it blends with the first heart sound and thus, in combination with the mitral and tricuspid closure sounds, contributes to the "first-sound complex."[1,2]

Atrioventricular block is a clinical condition in which the atrial and ventricular contractions may occur sufficiently apart so that the atrial sound and the main part of the first heart sound can be heard separately.

The Cambridge Audio-Visual phono-cardiograph can be used in studying the characteristics of the atrial sound. The microphone is a bell-type of 5 cm. diameter. The frequency characteristics of the instrument are favorable for detecting low-pitched vibrations, and the oscilloscope permits the physician to observe the visual display of the vibrations as he hears the sounds. Finally, a magnetic tape recording may be made and the record replayed and examined at leisure.

Methods

Patients with either first-degree or complete A-V block were studied after auscultation with the conventional stethoscope suggested that the atrial sounds were audible. The patients' heart tones were recorded with the Cambridge Audio-Visual phonocardiograph. Often much patience was required in exploring the precordium in order to find the area where the atrial sound could be best heard. A simultaneous electrocardiogram was recorded on a separate machine.

Results

Thirty patients with varying degrees of A-V block were studied, most of whom demonstrated atrial sounds. Of special interest are four cases in which the atrial sounds during some cardiac cycles appeared to be split into two components. A photographic display of the phonocardiogram and the separate electrocardiogram of each of these patients is shown in Figures 1 to 4.

---

*Mount Sinai Hospital.

Discussion

Splitting of the atrial sound could be demonstrated in four patients during some but not all cardiac cycles. The split was demonstrated best whenever the P-wave (and the atrial contraction) fell between ventricular contractions. There was no difference in clinical characteristics between patients with split atrial sounds and those with unsplit atrial sounds.

It is possible that in some patients the contraction of the right and left atria, in sequence, results in separate sounds that can be detected as a split atrial sound. In most clinical situations, however, the sounds associated with right and left atrial contractions are close together and are recorded as a single, fused atrial sound.

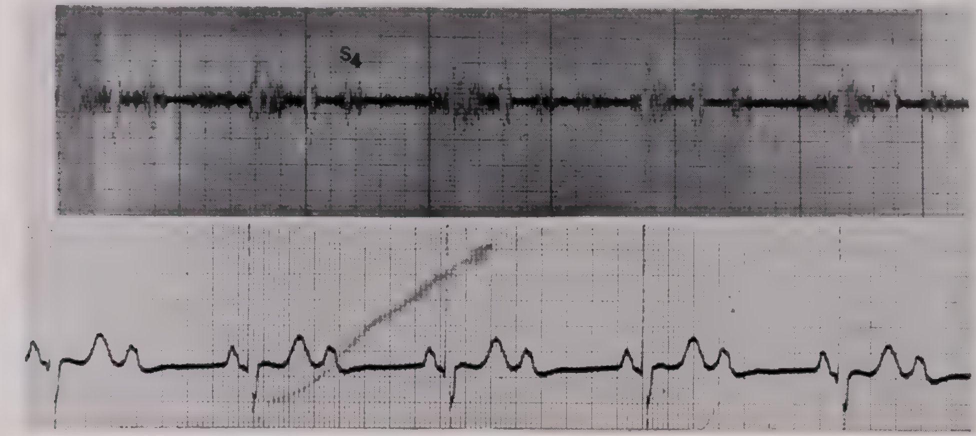

Figure 1

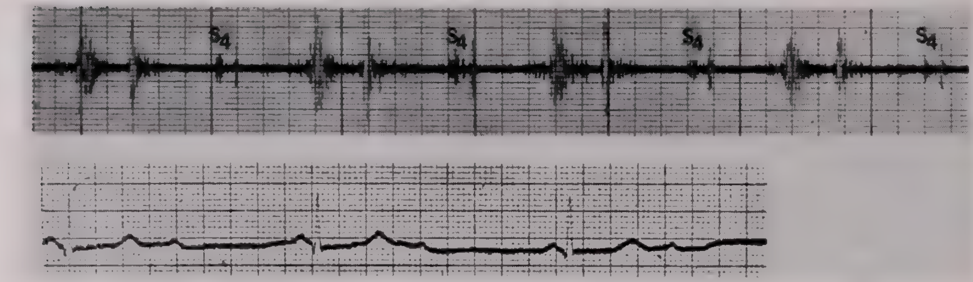

Figure 2

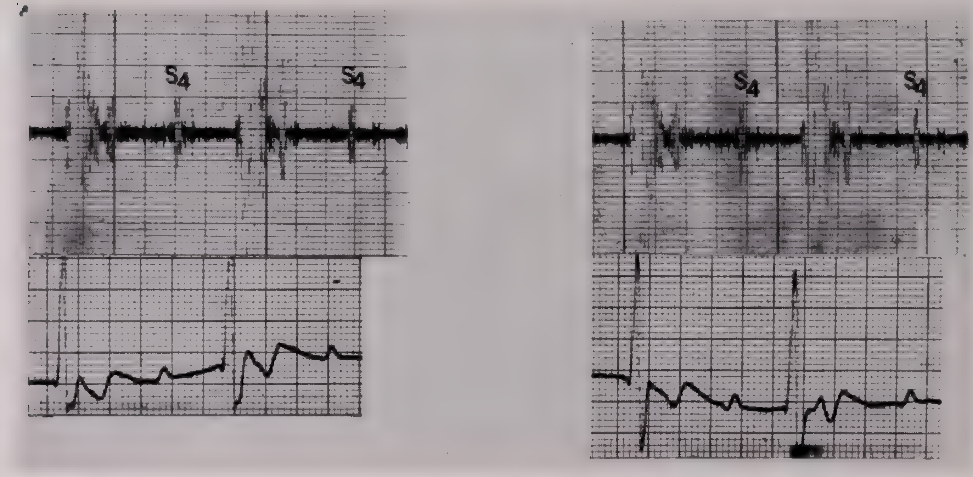

Figure 3

Several reports in the literature contain illustrations in which the atrial sounds appear to be split. Rytand's[3] "atrial murmur" may be a variant of a split atrial sound. Merrill, et al.[4] recorded "doubled" atrial sounds transmitted along the radial artery. Heyman[5] recorded atrial waves of a "double wave form" over the brachial and radial arteries. Butterworth[1b] has described split atrial sounds.

The phenomenon of the splitting of the atrial sound is demonstrable only under special conditions, such as A-V block, when the atrial sound is far enough removed from the ventricular sound so that it is not obliterated by the first and second heart sounds.

Inspection of the phonocardiographs shows that the two components of the split atrial sound have a slightly different configuration. A hypothesis may be suggested to explain this: The atrial contraction pumps blood into the ventricle and the ventricular wall bulges outward producing a "thud"—the atrial sound (fourth heart sound). This sequence occurs in the right and left ventricles. The wall of the right ventricle is thinner than that of the left ventricle; consequently the "thud" produced by the right ventricle produces a different phonocardiographic image than the "thud" produced by the left ventricle.

Conclusion

With the aid of an audio-visual phonocardiogram four patients with A-V blocks were found to exhibit splitting of the atrial sound. The mechanism of this splitting is discussed.

Case Summaries

Case 1: Age 79. Height 66 inches, weight 180 lbs. Blood pressure 250/100. Presenting symptom: Dyspnea, 2:1 to 3:1 A-V block. Treatment: Intravenous demand-type pacemaker.

Case 2: Age 71. Height 63 inches, weight 102 lbs. Blood pressure 130/80. Presenting symptom: Dizziness, 2:1 to 3:1 A-V block. Treatment: Intravenous pacemaker.

Case 3: Age 54. Height 68 inches, weight 150 lbs. Blood pressure 140/80. Presenting symptoms: Weakness, dizziness, First-degree A-V block.

Case 4: Age 88. Height 68 inches, weight 164 lbs. Blood pressure 120/80. Parkinsonism. First-degree A-V block.

For elderly patients in need of a mild tranquilizer consider **Tybatran®**

brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

A. H. Robins Company, Richmond, Va. 23220

A-H-ROBINS

Save him from RHEUMATIC FEVER

Here are two ways:

1. If your child has a bad sore throat, don't wait – it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...
so more will live
HEART FUND

Division Physicians and Hospitals Supply Co.,
THE ULMER PHARMACAL COMPANY
Minneapolis, Minnesota 55403

Dear Doctor:

Two common geriatric and pre-geriatric vasospastic states, cerebral ischemia and myocardial ischemia, have been shown to be helped by papaverine when administered in a form which provides gradual release of the drug. Just such a form for continued release is found in VASOSPAN containing 150 mg. of papaverine hydrochloride in an efficient sustained-release capsule.

"Emphasis on Flow" is the aim of treatment and the accomplishment of VASOSPAN in these conditions. And it's done economically, too—a matter of no little importance to the geriatric or pre-geriatric patient. With VASOSPAN there is a comparatively rapid early release for prompt relief, and a prolonged release for continued relief.

The following benefits can be expected from sustained-release papaverine with regard to the forgetfulness, confusion and irritability of cerebral ischemia or the recurrent anginal discomfort of myocardial ischemia:

Pharmacologically, papaverine acts on cardiac and smooth muscle[1,2] including the arterial musculature of cerebral[2] and coronary[3] vessels.

Clinically, papaverine is employed for its vasorelaxant (dilator) action rather than an analgesic in coronary vasospastic conditions[4] and for symptomatic benefit in cerebral ischemia not caused by advanced arteriosclerosis.[5,6]

Sincerely,

A. W. Wilber

"Emphasis on Flow"

VASOSPAN™

(papaverine HCl 150 mg.)

Sustained Release Capsules

Each capsule contains papaverine hydrochloride, 150 mg., in timed disintegration pellets for sustained release. Class M exempt drug. *Indications:* Relief of cerebral and peripheral ischemia associated with arterial spasm, and myocardial ischemia complicated by arrhythmias. *Side Effects:* Rarely nausea, abdominal distress, anorexia, constipation, malaise, drowsiness, vertigo, sweating, headache. *Contraindications:* Use with caution in patients with glaucoma. *Dosage:* 1 capsule every 12 hours. May be increased to 1 capsule every 8 hours.

The Differential Diagnosis of Sudden Cerebral Deficit*

One of the more perplexing problems in medicine is the sudden abrupt alteration in cerebral function of a patient. These changes are variable and may consist of simple loss of consciousness, sudden vertigo, motor paralysis, sensory irritation or deficit, aphasia, visual loss, diplopia, dysarthria, dysphagia or incoordination. These are the more common forms and each is quite frequently encountered. These deficits may clear or persist. Those that clear may represent a seizure discharge, but more often in the older age group they are manifestations of ischemia or infarction of the parenchyma of the brain.

Seizures

The factors which favor the diagnosis of a seizure are classical. Previous history of similar deficits can be expected in seizure disorders. The history of progression from the described deficit to unconsciousness of short duration some time in the past is evidence of a seizure. The unconscious period of such a seizure often includes clonic or tonic muscle movement, incontinence or a fall; or it is followed by a short period of confusion, headache or drowsiness. If the diagnosis is seizure there should be a suggestive history as to etiology.

Trauma

If mechanical trauma is to be incriminated, it should have produced a period of unconsciousness requiring medical observation and/or hospitalization with some post-traumatic symptoms of headache, nausea or vomiting and a period of retrograde amnesia.

Infection

If infection is to be considered significant, there must have been an episode requiring hospitalization for known meningitis or encephalitis or an established exanthematous disease with associated "fever convulsions", delirium or coma.

Neoplasm

If a new growth is to be accepted as the etiology, then progressive focal neurological deficit needs historical documentation. Then and only then is the diagnosis of a seizure to be entertained in a patient with this type of complaint.

---

*Presented at the Minnesota Academy of General Practice Convention, Hotel Radisson, Minneapolis, Minnesota.

Cerebral Infarctions

If the sudden cerebral deficit does not fit the criteria of seizure but still persists as a deficit or has caused concern to the patient it must be considered a suspect cerebral infarction.

Cerebral infarctions generally occur deep within the white matter of the hemisphere, adjacent to the basal nuclei.

Motor System

Such infarctions may directly involve the corticospinal and corticobulbar pathways which control movement of the contralateral side of the body, but many do not. Those which do not involve the motor system cannot be expected to appear as a classical "stroke syndrome." The infarct which lies adjacent to the motor pathways or marginally in these pathways may produce only a transient motor deficit. Many of these will leave a most subtle persisting deficit, one which is found only on very careful neurological examination. If after a sudden hemiparesis which has "cleared" there is a minimal hyperreflexia, a suggestive Babinski sign or a loss of motor endurance, then it becomes sufficient evidence to substantiate a diagnosis of infarction.

Sensory Area

If the sudden cerebral deficit consists only of a sensory hallucination or deficit with minimal or no motor component, then the possibility of the infarct lying within the thalamoparietal radiations should be considered. A deficit of the sensory realm is quickly accommodated to by the patient, and only on a searching neurological examination will one find evidence of persisting damage. Lesions within this system may produce an astereognosis* of a contralateral side; the patient may not be able to identify objects placed in the hand by non-visual clues alone. Numbers written on the arms or hands, out of his view, may not be identified correctly on one side of the body. Fixed position of his extremities, the outstretched hands, may not be held symmetric when the eyes are shut. These findings may be as good as a paralysis for establishing a diagnosis of infarction of a more posterior site. Even more subtle sensory deficits of a very minimal hemihypesthesia or a hemihypalgesia may signify an infarct.

Visual Field

If the complaint is visual then tangent screen examination of the visual fields becomes mandatory. Patients, especially of the younger adult group, who develop a field defect may learn to accommodate rapidly and be unaware that a deficit persists. Tangent screen examination produces information which may well localize the lesion.

Aphasias

Sudden aphasias must be examined most carefully. Here the patient's own account is of great value: he may tell you he no longer can calculate or read or comprehend spoken words as rapidly as before. He may no longer be able to "find words" or to name objects or symbols as automatically as previously. This history is evidence of a cerebral infarction in the region of speech formulation, the posterior left hemisphere.

If the transient cerebral deficit has been one of diplopia, facial paresis, facial paresthesias or bulbar deficit and/or incoordination, then the diagnosis will be infarction; seizures do not often have such patterns. To detect a persisting deficit becomes most important since it determines the therapy. If it is overlooked it may well jeopardize the medical well-being of the patient.

---

*See Test Your Word Score Page 1637.

Posterior Circulation Infarction

Basilar Vertebral Vessels

A transient or partial bullar palsy strongly suggests a vascular deficit in the distribution of the basilar vertebral circulation. This deficit associated with true vertigo is even more confirmatory. Previous history of alternating hemimotor, hemisensory or hemianoptic defect also incriminates this major circulation as the source of the pathology. True "dropping spells" also are almost exclusively due to basilar vertebral pathology in the older age group.

Superior Cerebellar Artery

Sudden transient or persisting diplopia associated with a unilateral incoordination should lead one to conclude that the vascular bed perfused by the Superior Cerebellar Artery has manifest ischemia or infarction. Other signs of this lesion are variable and unreliable.

Anterior Inferior Cerebellar Artery

Sudden facial paralysis and/or vertigo which remisses requires a careful search for unilateral cerebellar incoordination which would signify an infarct in the anterior inferior cerebellar artery distribution.

Posterior Inferior Cerebellar Artery

The sudden lateral medullary syndrome, the Wallenberg syndrome, consisting of a loss of bulbar function with vertigo and dysphagia, an ipsilateral facial hypesthesia, ipsilateral incoordination and contralateral body hypesthesia may rapidly subside, leaving only a minimal deficit. The presence of even a subtle incoordination confirms the fact that an infarct has occurred and permits the indicated therapy to be initiated without jeopardizing the health of the patient.

These, the clinically common forms of sudden cerebral deficit, are not difficult to diagnose. It is more difficult when no signs remain and the area involved is truly "silent." The concept of "transient ischemic attack" is probably the term to be applied to these infarcts which occur in areas of the brain which do not have direct externalization of their function in terms of motor, sensory, speech or visual performance.

Thought

Few people think more than two or three times a year. I have made an international reputation by thinking once or twice a week.—George Bernard Shaw

Pertofrane® desipramine hydrochloride

Indication. Mental depression.

Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal.

When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed.

The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants.

Warning: Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm.

Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold).

Desipramine and the parent compound, imipramine, have been shown to block the action of guanethidine and related adrenergic neuron-blocking agents.

Hypertensive episodes have been observed during surgery.

The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures.

Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery.

Do not use in women who are or may become pregnant unless the clinical situation warrants the potential risk, and do not use in patients under 12 years of age.

Because of increased sensitivity to the drug, use lower than-normal dosage in adolescent and geriatric patients.

Precautions. Potentially suicidal patients require careful supervision and protective measures during therapy. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement.

Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents).

Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances.

Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy.

Adverse Reactions. The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.

Dosage. All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily.

Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response.

Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated.

Availability: Maroon and pink capsules of 50 mg. in bottles of 100, pink capsules of 25 mg. in bottles of 100 and 1000.

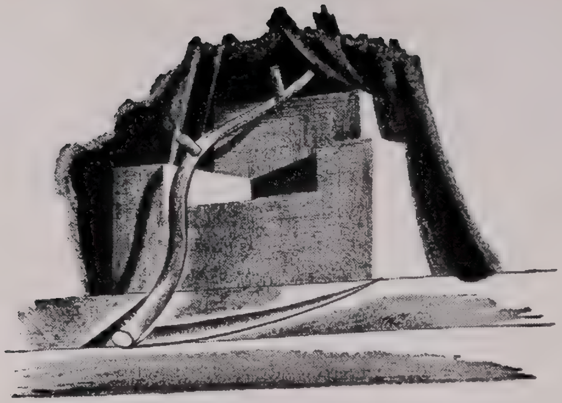
It's beautiful!



In Memoriam

The eternal stars shine out as soon as it is dark enough.—Carlyle

C. KENNETH COOK, M.D.

Dr. C. Kenneth Cook, 68, St. Paul surgeon, died July 2. A native of New London, Iowa, Dr. Cook was a resident of St. Paul for 37 years. He retired after 30 years from his Payne Avenue medical practice in 1962. He was an alumnus of the University of Iowa and graduated from the University of Michigan Medical School in 1927.

Dr. Cook was a member of the Ramsey County Medical Society, the American Medical Association, a fellow of the American College of surgeons and the International College of Surgeons, and an Associate Member of the Minnesota State Medical Association. He was chief of staff at St. Johns' Hospital in 1951 and 1952.

He is survived by his wife, a daughter and a son.

ARTHUR WILLIAM NUETZMAN, M.D.

Dr. Arthur W. Nuetzman, 66, a practicing physician and surgeon in Faribault for 35 years, died May 24. A graduate of the University of Minnesota School of Medicine, Dr. Nuetzman interned at the Charles T. Miller Hospital in St. Paul before establishing his Faribault practice.

Dr. Nuetzman had served as Rice County coroner for over 20 years and had been physician for the Minnesota State Braile and Sight Saving School in Faribault since 1935. He was a member of the medical staff of the Rice County District One Hospital, the Rice County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife and one son.

HAMLIN A. N. MATTSON, M.D.

Dr. Hamlin A. N. Mattson, 69, Minneapolis surgeon for 37 years, died June 28. Born in Tacoma, Washington, Dr. Mattson obtained his medical degree at the University of Minnesota.

He was a past president of the American Swedish Institute, a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, a son and two daughters.

CLAYTON K. WILLIAMS, M.D.

Dr. Clayton K. Williams, 78, St. Paul physician, died June 27, following a short illness. Born in Minneapolis but a resident of St. Paul for the past 40 years, Dr. Williams received his medical degree from the University of Minnesota.

He was a former secretary and a past president of the Ramsey County Medical Society and was a member of the Minnesota Academy of Medicine, American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife.

DAN W. FISHER, M.D.

Dr. Dan W. Fisher, 65, St. Paul physician, died May 14. Born in Ellwood City, Pennsylvania, Dr. Fisher obtained his medical degree at the University of Michigan.

He was a member of the Ramsey County Medical Society, the American College of Physicians, the Minnesota State Medical Association and the American Medical Association.

Dr. Fisher is survived by his wife, a son and a daughter.

RAMBY C. RASMUSSEN, M.D.

Dr. Ramby C. Rasmussen, 78, St. Paul surgeon, died May 23. Born in Denmark, Dr. Rasmussen received his medical degree from the University of Minnesota.

He was a member of the Ramsey County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Rasmussen is survived by his wife and a son.

JOSEPH L. MARTINEAU, M.D.

Dr. Joseph L. Martineau, 81, St. Paul surgeon, died June 6. Born in St. John, North Dakota, Dr. Martineau had lived in St. Paul for the past 55 years. He established a medical practice in St. Paul in 1915.

He was a member of the American Medical Association, the Ramsey County Medical Society, the American Academy of General Practice, and a 50 Club and Life Member of the Minnesota State Medical Association. His medical degree was received from Rush Medical College, University of Chicago.

He is survived by his wife, three daughters and a son.

WILLIAM B. McMURTRIE, M.D.

Dr. William B. McMurtrie, 71, Minneapolis physician, died May 26. A graduate of the University of Minnesota Medical School, Dr. McMurtrie practiced in Marble and Hutchinson, Minnesota, before opening offices in Minneapolis.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife and two daughters.

CLARENCE O. MALAND, M.D.

Dr. Clarence O. Maland, 87, Minneapolis obstetrician and gynecologist at the Swedish Hospital, died June 14.

He was assistant professor of obstetrics and gynecology at the University of Minnesota Medical School, during his tenure at the Swedish Hospital.

Dr. Maland was a member of the College of Surgeons, the Hennepin County Medical Society and American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife and a daughter.

SOLVEIG T. GISLASON, M.D.

Dr. Solveig T. Gislason, 78, St. Peter physician and teacher, died June 12. A graduate of the University of Minnesota Medical School, she first practiced medicine in Marshall, when her husband, Judge Gislason, was assigned there, and later practiced in New Ulm. From there she went to St. Peter where after practicing for 15 years retired from practice last year.

She was a member of the Nicollet-LeSueur County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Gislason was survived by three sons and a daughter.

LESLIE CAPLAN, M.D.

Dr. Leslie Caplan, 61, Minneapolis psychiatrist, died August 4. He was a graduate of Ohio State University and the Ohio State University Medical School.

A clinical associate professor at the University of Minnesota and a consultant at the Veterans Hospital in Minneapolis, Dr. Caplan was a member of the American Medical Association, the Minnesota State Medical Association, the Hennepin County Medical Society, a fellow of the American Psychiatric Association and a past secretary of the State Association.

He is survived by his wife and two daughters.

DAVID S. THORSEN, M.D.

Dr. David S. Thorsen, director of the Wilder Child Guidance Clinic, died July 4. He was 52.

Born in Minneapolis, Dr. Thorsen attended the University of Minnesota and received his medical degree from the University's College of Medicine. In recent years he had been a consultant to the Hennepin County Welfare Department, the Lutheran Social Service and the Washington County Juvenile Court.

Dr. Thorsen was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society.

He is survived by his wife, three daughters and two sons.

RICHARD H. SEARL, M.D.

Dr. Richard H. Searl, 36, Faribault physician, died June 19. He graduated from the University of Kansas Medical School in 1957 and interned at Ancker Hospital in St. Paul.

Dr. Searl was presently serving as secretary-treasurer of the Southern Minnesota Medical Association and was president of the Southern Minnesota Chapter of the Minnesota Academy of General Practice, chairman of the Membership and Credentials Committee of the Minnesota Academy of General Practice and chairman of the General Practice Club at the University of Minnesota. He was also a member of the American Medical Association, the Minnesota State Medical Association and the Rice County Medical Society.

He is survived by his wife, a son and daughter.

WILLIAM W. WILL, M.D.

Dr. William W. Will, 90, Bertha physician for more than 50 years, died July 11. Born in Blue Earth County, he received his medical degree from the University of Minnesota Medical School.

For fifteen years he was president of the Todd County Medical Club. In addition, Dr. Will was a member and former president of the Upper Mississippi Medical Society; member and former president of the Northern Minnesota Medical Society; member, president for one year, councilor, 12 years, speaker of the House of Delegates for nine years and a Life and 50 Club Member of the Minnesota State Medical Association; trustee and vice president of the Minnesota Medical Foundation of the University of Minnesota; member and director, Minnesota State Sanitary Conference; member of the Fair Oaks Lodge Sanatorium Commission and a Fellow of the American College of Surgeons and the International College of Surgeons.

Dr. Will is survived by two sons and daughters.

CHARLES L. SHERMAN, M.D.

Dr. Charles L. Sherman, 92, retired Luverne physician and surgeon, died July 8. Born at Canton, South Dakota, Dr. Sherman received his medical degree from Barnes Medical School in St. Louis.

Dr. Sherman was one of the men who foresaw the need of a sanitarium for tuberculosis in southwestern Minnesota and had been active in the organization of an eight-county district to fight the dreaded disease.

The late Governor Christianson appointed him to serve on the Minnesota Board of Medical Examiners in 1927, a position which he held until a few years ago. He served as president of the Southwestern Minnesota Medical Association, was president of the Southern Minnesota Medical Association, and headed at one time the Sioux Valley Medical Society. He was a member of the American Medical Association and was a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Sherman is survived by his wife and son.

FREDERICK N. SOLSEM, M.D.

Dr. Frederick N. Solsem, 90-year-old Spicer physician, died July 7. He attended Loyola University Medical School in Chicago and resumed his private practice at Spicer in the early 1930s.

He was a member of the American Medical Association and Kandiyohi-Swift-Meeker Medical Society and a 50 Club and Life Member of the Minnesota State Medical

Association.

Dr. Solsem is survived by his wife and one daughter.

THOMAS S. McCLANAHAN, M.D.

Dr. Thomas S. McClanahan, 77, a long-time White Bear Lake physician, died August 1, after a short illness. He was born in Kirkwood, Illinois, and had been a resident of St. Paul since 1919, when he began his medical practice.

He was a member of the American Medical Association and Ramsey County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association. A long-time staff member at St. John's Hospital, Dr. McClanahan was chief of staff there from 1954 to 1955. He retired in 1966.

Dr. McClanahan is survived by his wife, two daughters and a son.

ROBERT P. CARON, M.D.

Dr. Robert P. Caron, 70, Minneapolis surgeon, died August 3. Born in Illinois, Dr. Caron attended the University of Illinois Medical School, graduating in 1925.

He was a member of the American Medical Association and the Hennepin County Medical Society and a Life Member of the Minnesota State Medical Association.

Dr. Caron is survived by his wife and daughter.

DAVID I. SEIBEL, M.D.

Dr. David I. Seibel, 47, assistant professor of obstetrics and gynecology at the University of Minnesota, died August 17. A graduate of the City College of New York and the University of Rochester, New York Medical School, Dr. Seibel came to Minneapolis twenty-two years ago.

He was a diplomate of the American Board of Obstetrics and Gynecology and a member of the American Medical Association, the Minnesota State Medical Association, the Minnesota State Obstetrics and Gynecology Association, Hennepin County Medical Society, American Society of Cystology and the Minnesota Medical Foundation.

Dr. Seibel is survived by his wife, two sons and a daughter.

EJVIND P. K. FENGER, M.D.

Dr. Ejvind Fenger, 72, of Chanhassen, director of tuberculosis services for the Minnesota State Department of Health since 1961, died July 25.

A nationally recognized clinical specialist in pulmonary diseases, he coordinated the state and local tuberculosis control services of the department and directed the tuberculosis control and treatment program in all state institutions for the Department of Public Welfare.

Born in Denmark, Dr. Fenger grew up in Askov, Minnesota. He received his medical degree from the University of Minnesota in 1924 and was on the medical staff of the Glen Lake Sanatorium for 36 years.

Dr. Fenger was one of only 91 board-certified, full-time specialists in pulmonary diseases in the nation. He was a member of the American Medical Association and the Hennepin County Medical Society and a Life Member of the Minnesota State Medical Association.

He is survived by his wife and two daughters.

HENRY WILLIAM MEYERDING, M.D.

Dr. Henry William Meyerding, 84, a member of the section of Orthopedic Surgery of the Mayo Clinic from 1910 to 1949, and professor of orthopedic surgery in the Mayo Graduate School of Medicine of the University of Minnesota, died August 27. Born in St. Paul, he received his doctor of medicine from the University of Minnesota. He went to Rochester in 1910 as special assistant to Doctors William J. Mayo, Charles H. Mayo and E. Starr Judd.

Dr. Meyerding received the degree of master of science in orthopedic surgery in 1918, the first to be given by the newly established Mayo Graduate School of Medicine of the University of Minnesota. From 1918 he was instructor in orthopedic surgery in the Mayo Graduate School of Medicine; from 1920 to 1922 he was assistant professor; from 1922 to 1937 he was associate professor; and from 1937 to 1949 he was professor. On his retirement in 1949 he became an emeritus professor.

In 1923 he prepared an exhibit on tumors of bone which became a permanent exhibit in the Wellcome Museum of Medical Sciences in London, England.

Among the many positions he held are: president of the Clinical Orthopaedic Society in 1926; president of the Southern Minnesota Medical Association, first national member chairman of the American Academy of Orthopaedic Surgeons. He was one of the founders of the World Medical Association in 1948 and was elected president of the International College of Surgeons in 1958; he was president of the American Fracture Association and had been chairman of the section on Orthopaedic Surgery of the American Medical Association.

He was a member of the Zumbro Valley Medical Society and an Associate and 50 Club Member of the Minnesota State Medical Association.

Dr. Meyerding is survived by four grand children and two great-grand children.

FRANCIS RAYMOND KEATING, M.D.

Dr. F. Raymond Keating, Jr., 58, and his wife were killed in an automobile accident September 13. He was a Mayo Clinic specialist in metabolic diseases and considered one of the top researchers in that field. A native of Philadelphia, Dr. Keating was graduated from Cornell University; became a resident at the Mayo Graduate School and in 1941 was appointed an assistant to the clinic staff.

He was a senior consultant at the Clinic and a professor in the University of Minnesota Mayo Graduate School of Medicine.

Dr. Keating was a member of the Zumbro Valley Medical Society, the American Medical Association and the State Medical Association.

Today, more and more medical clinics —even two and three-doctor groups— are becoming incorporated so they can benefit from the income-tax savings that are possible when corporate profit-sharing trust funds are established.

And many of these groups are currently making use of our comprehensive investment management service that features continuous supervision of profit-sharing funds. In addition, we provide full administrative services, including: monthly statements of trust, annual reports for participants, preparation of tax forms, and custody of securities.

For more information, just fill out the attached postage-paid card and drop it in the mail.

Book Reviews

That is a good book which is opened with expectation and closed with profit.—
Amos Bronson Alcott

PIE IN THE SKY; THE MAKING OF AN AIRLINE STEWARDESS. By Marcia Norgaard. 165 pp. 1969 Exposition Press. New York. $4.50

Marcia Norgaard, ex-airline stewardess for Northwest Airlines, has invented North American Airlines, suspiciously like Northwest Airlines, to provide the vehicle for what must be (to some extent) autobiography molded to the shape of a novel. Her story of Kip Miller's progress through stewardess training and into a flying career is so absorbing that I found the book impossible to put down. Minnesota readers will recognize the locale of much of the action in and around Wold Chamberlain Airport. I suspect Mrs. Norgaard's main purpose in writing this book was to publish her address to high school senior girls on a flying career for women. But with it she has professionally written an account of an interesting career. And I must remember to ask Mrs. Norgaard what she meant by her subtitle.

CHRONIC ULCERATIVE COLITIS. By J. Arnold Bargen, M.C., Pages: 123, Illustrations: 26, Publisher: Charles C Thomas, Springfield, Illinois.

This short monograph, Ulcerative Colitis, is an interesting review of a lifelong study by the author.

It is well organized and covers briefly the broad field of ulcerative colitis in six chapters. The index is not comprehensive but is adequate for the size of the monograph. For a fascinating few hours of study or review it is well worth possessing.

Carl O. Rice, M.D,
Minneapolis, Minnesota

YOUR COMMUNITY HOSPITAL. By Robert Walsh. Beacon Press, $5.95.

This book, written by Robert E. Walsh, a reporter, is a successful attempt to rid the general public of the outmoded idea that a hospital is a collection of beds and medical equipment to be used only in spells and may help the public to better understand the emerging role of the hospital as a coordinating point for the health care of the community.

The book is recommended for reading by lay individuals who either contemplate hospital care or who are interested in the hospital as a place in the community.

Most people give little serious thought to the state of their community hospital until a health emergency arises; then when an understanding of how hospitals work would be most useful, their confusion and lack of information prevent them from utilizing its benefits efficiently. YOUR COMMUNITY HOSPITAL was written in order to improve this situation and to help American communities develop an active interest and participation in the affairs of their hospitals.

Mr. Walsh has accurately portrayed the community hospital. This is evident by the insight that he has gained about the problems and successes, the shortcomings and controls that affect the organization of a modern hospital. Questions are many but not uncomplimentary.

The author gives an excellent definition of the physician for the benefit of the layman. He illustrates some of the dilemmas physicians face, such as house calls, fees, etc. He provides an excellent explanation of the hospital-based specialist.

His conclusions are optimistic and, although he portrays some situations that are less satisfactory than they might be, his picture of a hospital is not as frightening as the occasional scandal report insists.

*Administrator, St. Barnabas Hospital.

TOBACCO AND YOUR HEALTH. Author: Harold S. Diehl, M.D., Special Consultant, American Cancer Society. Publisher: McGraw-Hill Book Company, New York.

This interestingly compiled monograph pertaining to the ill effects of cigarette smoking makes interesting, informative and worthwhile reading.

The habit of smoking is extremely difficult to eliminate but, after one has read this monograph and learned the numerous hazards, one should also realize the tremendous value of eliminating the habit. It is interesting to note that after one has managed to control the smoking habit the danger from carcinoma of the lung disappears in large part. Unfortunately, some of the less spectacular diseases, namely chronic bronchitis and peripheral vascular changes which can be almost as bad as cancer because of the continuing prolonged harmful effects, are not as easily eliminated after the cessation of smoking.

Surely this monograph can be advantageously recommended to the smoker who desires to discontinue the habit.

Carl O. Rice, M.D.

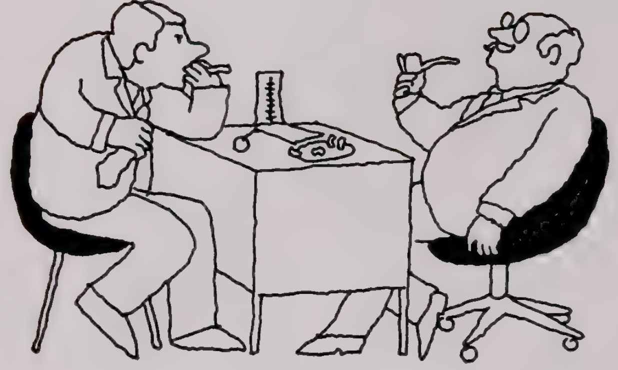
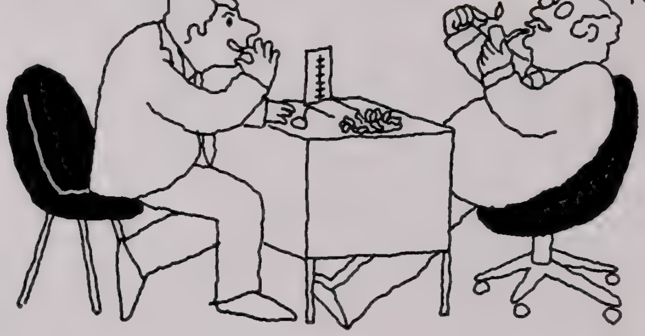
The Apprehensive Hypertensive



WELL, YOU HAVE WHAT WE CALL MODERATE HYPERTENSION– HIGH BLOOD PRESSURE. NOW I DON'T WANT YOU TO WORRY, BUT WE ARE GOING TO HAVE TO CHANGE A FEW LIVING HABITS. FIRST, WE'RE GOING TO HAVE TO CUT OUT SMOKING–ALTOGETHER.



THEN WE HAVE TO LOSE WEIGHT. 20 POUNDS SHOULD DO IT... WE'LL TALK A LITTL LATER ABOUT THIS DIET WE'RE GOING TO START.

Regroton® to lower blood pressur

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Regroton®: chlorthalidone 50 mg., reserpine U.S.P. 0.25 mg. *Indications:* Hypertension. *Contraindications:* History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. *Warning:* With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Inc respiratory secretions, nasal congestion, cyanosis and anorexi occur in infants born to reserpine-treated mothers. *Precautions:* pertensive therapy with this drug should always be initiated cau in postsympathectomy patients and in patients receiving gan blocking agents, other potent antihypertensive drugs, or curare. F dosage of concomitant antihypertensive agents by at least one-h avoid hypotension during surgery, discontinue therapy with this two weeks prior to elective surgical procedures. In emergency s use, if needed, anticholinergic or adrenergic drugs or other sup measures as indicated. Because of the possibility of progres renal damage, periodic kidney function tests are indicated. Disc if the BUN rises or liver dysfunction is aggravated. Hepatic com be precipitated. Electrolyte imbalance, sodium and/or potassi pletion may occur. If potassium depletion should occur during th the drug should be discontinued and potassium supplements provided the patient does not have marked oliguria. Take particul in cirrhosis or severe ischemic heart disease and in patients re

WE'VE GOT TO GET PLENTY OF REST AND TRY TO AVOID SITUATIONS THAT MAKE US ANXIOUS OR TENSE. AND WE'LL TAKE MEDICINE TO LOWER OUR BLOOD PRESSURE AND CALM US DOWN.

WE'VE GOT PROBLEMS.

nd allay anxiety in hypertension

costeroids, ACTH, or digitalis. Severe salt restriction is not recom-
ed. Use cautiously in patients with ulcerative colitis or gallstones
ry colic may be precipitated). Bronchial asthma may occur in
eptible patients. *Adverse Reactions:* The drug is generally well
ted. The most frequent side effects are nausea, gastric irritation,
ing, diarrhea, constipation, muscle cramps, headache, dizziness
acute gout. Other potential side effects include angina pectoris,
ty, depression, bradycardia and ectopic cardiac rhythms (espe-
when used with digitalis), drowsiness, dull sensorium, hypergly-
a and glycosuria, hyperuricemia, lassitude, restlessness, transient
ia, impotence or dysuria, orthostatic hypotension which may be
tiated when chlorthalidone is combined with alcohol, barbiturates
rcotics, leukopenia, aplastic anemia, skin rashes, thrombocyto-
, agranulocytosis, nasal stuffiness, increased gastric secretions,
nare, purpura, urticaria, ecchymosis, weakness, uveitis, optic
y and glaucoma, and pruritus. Eruptions and/or flushing of the
a reversible paralysis agitans-like syndrome, blurred vision, con-
val injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. *Average Dosage:* One tablet daily with breakfast. *Availability:* Pink, single-scored tablets in bottles of 100 and 1000. (B)46-600-C

For details, please see complete prescribing information.

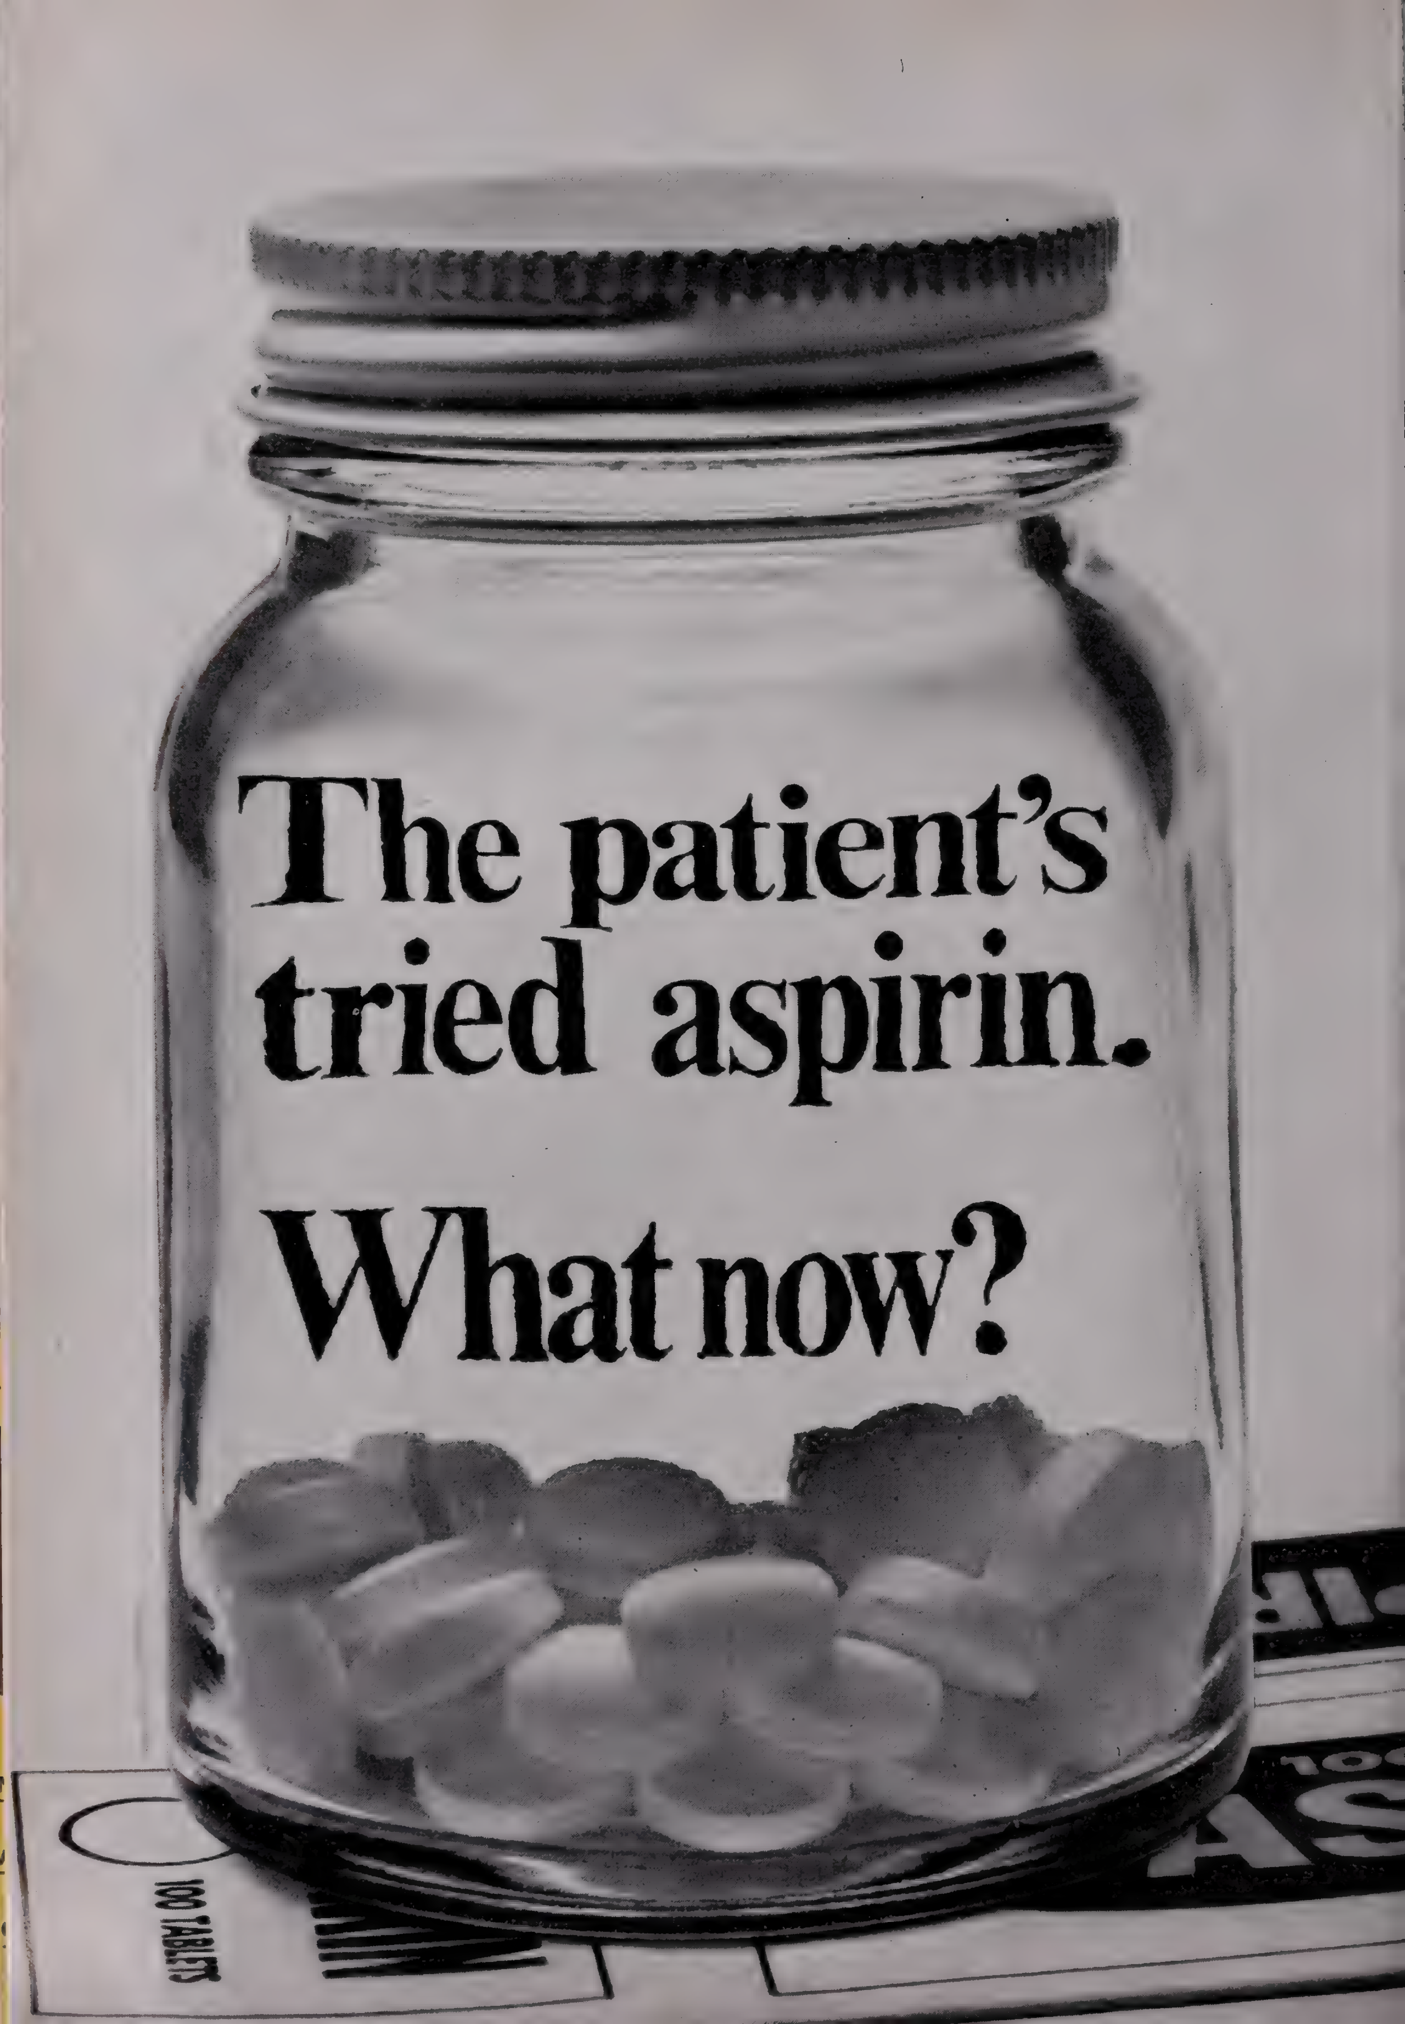
RE-6742



The patient's tried aspirin.
What now?
100 TABLETS

There's a good chance your patient needs more than a non-prescription analgesic for pain relief. Especially after self-medication has failed.

Because continuing, increased pain and discomfort may in part be a reflection of anxiety, Equagesic is worthy of consideration. In a single, non-narcotic preparation, it helps relieve pain . . . *and* associated anxiety and tension.

Tablets
Equagesic®
(meprobamate and ethoheptazine citrate with aspirin) Wyeth

IN BRIEF

Contraindications: History of sensitivity or severe intolerance to aspirin, meprobamate or ethoheptazine citrate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore, it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

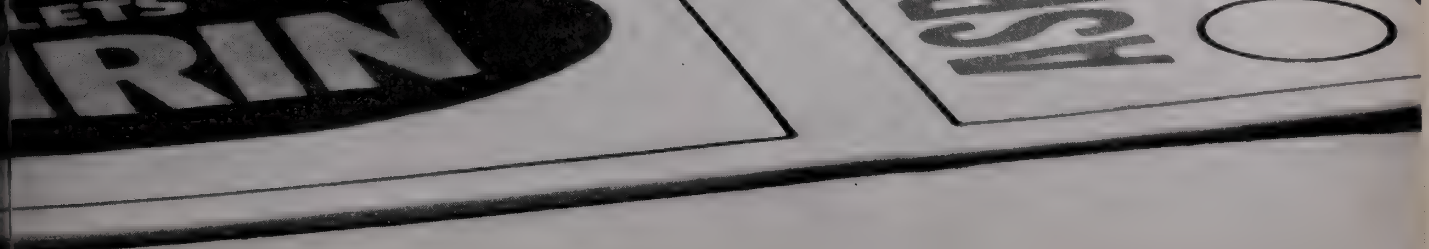
Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics—has resulted in dependence or habituation. Withdraw gradually after prolonged excessive dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance, with resultant slowed reactions and impaired judgment and coordination. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, patients should not operate machinery or drive. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously and in small amounts to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with gastric lavage and appropriate symptomatic therapy (CNS stimulants and pressor amines as indicated). Two instances of accidental or intentional significant overdosage with ethoheptazine and aspirin have been reported. These were accompanied by CNS depression (drowsiness and lightheadedness) but resulted in uneventful recovery. On basis of pharmacologic data, CNS stimulation could be anticipated, with nausea, vomiting and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]).

Adverse Reactions: Ethoheptazine and aspirin may cause nausea with or without vomiting and epigastric distress in a small percentage of patients. Dizziness is rare at recommended dosage. Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses. Such patients may have had no previous contact with meprobamate and may or may not have an allergic history. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, discontinue meprobamate; do not reinstitute. Severe reactions, observed very rarely, include fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. These cases should be treated symptomatically including, when indicated, such medication as epinephrine, antihistamine and possibly hydrocortisone. A few cases of leukopenia, usually transient, have been reported on continuous use. Rarely, aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported, almost always in presence of known toxic agents.

Overdosage: See precautions section for management of overdosage.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Wyeth Laboratories Philadelphia, Pa. Wyeth®



Minnesota Medicine Survey

Though you may or may not read it extensively, would you do us a favor, fill out the questionnaire and return it to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Indicate the approximate percentage of the time that you read the following items:

1. MINNESOTA MEDICINE. None, 25%, 50%, 75%, 100%.

2. The advertisements. None, 25%, 50%, 75%, 100%.

3. Indicate the percentage of time in which you read the following sections:

   ____ Scientific; ____ Editorials; ____ Letters to the Editor; ____ Editor's Soliloquy; ____ Quotes at the bottom of article; ____ Full page fillers; ____ Viewing Box; ____ CPC's; ____ Curbstone Consultations; ____ Fracture Conferences; ____ Tumor Conferences; ____ Grand Rounds; ____ Advances; ____ Reviews; ____ Physician's Workshop; ____ Special Articles; ____ Meetings & Announcements; ____ Lab Letters; ____ Physician's Diary; ____ Dermatology; ____ Abstracts; ____ Test Your Word Score; ____ Book Reviews; ____ History of Medicine; ____ In Memoriam; ____ Minnesota Medicine at a Glance.

4. Which section do you read the least ____________________.

5. Your Specialty ____________________? Resident ____________________?

Minnesota Medicine at a Glance

Treatment of Coronary Disease—*Edwards* Page 1587

Numerous advances in care of patients suffering from coronary artery disease have opened new avenues of treatment for several aspects of this widespread disease process. The anatomic limitations of these newer forms of treatment are discussed. Numerous fine photographs and photomicrographs clearly illustrate the problems discussed.

Thrombocytosis—*Silvis et al.* Page 1603

The records of 322 patients with thrombocytosis have been reviewed. The number of patients with thrombocytosis was 2.57 per cent of the hospital admissions for this period. Malignant disease was found in 64 per cent of the patients, whereas 36 per cent had benign conditions. Of the patients studied 9.9 per cent had thromboembolic complications after the thrombocytosis was discovered. Patients with thromboembolic disease had higher average platelet counts and hemoglobin concentration than those who did not develop this complication. The present study confirms the almost century-old observation that thrombocytosis is seen in a high number of patients with malignant disease. Although the mechanism of the platelet count elevation with malignant conditions is not clear, recognition of this association may be helpful in the diagnostic workup of patients.

Hematologic Toxicity of Chloramphenicol—*Mork* Page 1619

The magnitude of the chloramphenical mis-prescription problem is reviewed. A surprising number of delayed cases of myelogenous leukemia have occurred after non-fatal aplastic anemia following chloramphenical therapy.

Tumors in Children—*Mahour and Lynn* Page 1679

The authors present a brief but thorough survey of tumors in children, with statistical data pertinent to the differential diagnosis of these tumors as well as the clinical descriptions of each entity. They also include a review of the experience at the Mayo Clinic with soft tissue sarcomas of children from 1950 to 1965.

THEORY versus FACT

"However good a theory may be, it is never as good as the truth or as actual fact. I do not believe there is a single theory in physiology, or even in physics and chemistry, that is actually and absolutely true. Everything is merely relative. . . . It is therefore an excellent thing to have destroyed a theory. It is a step forward, and we must not quake when a fact destroys a theory, even our own—we must investigate. There is a discovery underneath, a revolution, as they say; for science is revolutionary, and does not advance by successive additions, as people believe it does."*

vol 52 #1

of Taxco, Mexico"

Donald A. Scholz, M.D.

NOVEMBER, 1969

Dear Doctor,
You made me
what I am today–
a whole lot
slimmer!

TEPANIL—the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence.

As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported.

Sympathomimetic *cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others.

Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema.

Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported.

Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia.

A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Tepanil® Ten-tab®
(continuous release form)
(diethylpropion hydrochloride)

LACTINEX®

TABLETS & GRANULES

■ to help restore and stabilize the intestinal flora

■ for fever blisters and canker sores of herpetic origin

Lactinex contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

Lactinex has been shown to be useful in the treatment of gastrointestinal disturbances, and for relieving the painful oral lesions of fever blisters and canker sores of herpetic origin.[1,2,3,4,5,6,7,8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

DECLOSTATIN® 300 b.i.d.

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropria
measures should be taken.

In infants, increased intracranial pressure with bulging fontanels h
been observed. All signs and symptoms have disappeared rapidly up
cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, dia
rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopa
ular and erythematous rashes; a rare case of exfoliative dermatitis h
been reported. Photosensitivity; onycholysis and discoloration of t
nails (rare). Kidney—rise in BUN, apparently dose related. Transie
increase in urinary output, sometimes accompanied by thirst (rare
Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylax
Teeth—dental staining (yellow-brown) in children of mothers given t
drug during the latter half of pregnancy, and in children given the dr
during the neonatal period, infancy and early childhood. Enamel hyp
plasia has been seen in a few children. If adverse reaction or idios
crasy occurs, discontinue medication and institute appropriate thera

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should
given 1 hour before or 2 hours after meals, since absorption is impai
by the concomitant administration of high calcium content drugs, foo
and some dairy products. Treatment of streptococcal infections shou
continue for 10 days, even though symptoms have subsided.

AMA
dENVER

plan to attend the 23rd ama clinical convention denver, colorado·november 30-december 3,1969

A bustling skyscraper-studded cosmopolitan city, Denver, Colorado is western in character and dotted with sophisticated shops, superb restaurants, and theaters. And, just minutes away, the great Colorado Rockies — with forests, lakes and tumbling streams, internationally known ski areas, ghost towns, hunting and fishing.

As a general practitioner or specialist, you will find the Denver winter medical meeting a highly rewarding experience. Scientific Program Sessions, Breakfast Roundtable Conferences, Clinical Workshops, Panel Discussions, Television, Medical Motion Pictures, and hundreds of Scientific and Industrial Exhibits to show you the latest in equipment, services, and drugs are some of the means of keeping up-to-date in medicine.

Be sure to look for the complete scientific program, plus forms for advance registration and hotel accommodations in the October 20th issue of JAMA.

Caution: Cigarette Smoking May
Be Hazardous to Your Health

If you give up cigarettes, you might gain a few pounds.

(And also a few years.)

The plain, unfiltered fact is that people who smoke cigarettes get lung cancer a lot more frequently than nonsmokers.

And lung cancer can finish you.

Before your time.

We'd rather have you stay alive and in good health.

Because even if you do gain a few pounds, you'll have the time to take them off.

Association of Minnesota Internists

THE ASSOCIATION OF MINNESOTA INTERNISTS is the State chapter of the American Society of Internal Medicine (ASIM). The National Society was formed in 1956 to provide internists with an organization to study and respond to socioeconomic and political forces affecting the cost, quality and availability of their services and to insure continuing professional competence of the internist in the practice of his speciality.

The action forming the new Society was supported by the American College of Physicians. The two Societies are now working closely through liaison committees from the presidential level on down. From a small beginning the Society has rapidly expanded and today numbers over 10,000 active members.

As all physicians soon discover, quality professional service cannot be separated from either the costs or the conditions under which it is provided.

The impact of Federal health care financing and the ever increasing governmental controls which are becoming more and more apparent should make us all realize that the things which are exerting major influences on our lives and on our goals in medicine are not happening in our offices but outside of them — largely in Washington, D. C.

We have recently heard the opening guns in a campaign to fix the blame for increasing Medicare costs. Even though Congress was warned that such would occur there is much feigned surprise today, and no small attempt is being made to place the blame for increasing costs on the physician. One of our aims is to vigorously evaluate the problems briefly referred to above and to find solutions not in recrimination but through constructive cooperation.

Health care has became a "right" of the American citizen. The mushrooming demands for medical services are beginning to tax not only the ingenuity but the physical endurance of the most dedicated physician. Either we must devise new methods of practice to handle all those demanding services or the government will do it for us.

In this sector the American Society of Internal Medicine is moving ahead in planning for the training of para-medical personnel. Much time and thought are going into methods of developing and using multiphasic health screening procedures. Labor management committees are helping to write new contracts that will bring medical care into proper perspective. Ways of increasing the number of medical graduates are being actively studied.

Propaganda fostered by both the Federal government and the prepaid hospital plans has made the use of the hospital bed much like the Christmas Club—"all paid for in advance." This of course has culminated in the problem of over-utilization and its foreseeable counteraction—that of governmental demand for com-

Hemolysis Associated with Intracardiac Prostheses

Diagnosis and Management

REX B. SHAFER, M.D.*
WILLIAM R. SWAIM, M.D.*
Minneapolis, Minnesota

HEMOLYTIC ANEMIA is a recognized complication of cardiac surgery. Two types have been described: first, a mechanical hemolytic anemia associated with repair of septal or atrioventricular canal defects,[1-4] and with valvular replacement with an intracardiac prosthesis;[5,6] and second, a type of hemolytic anemia associated with valve replacement, which is thought to be on an auto-immune basis.[7]

The purpose of this report is to illustrate the character and mechanism of the mechanical hemolysis associated with the use of the Starr-Edwards aortic valve in two patients, one of whom was anemic. The diagnosis, conservative management, and effect of exercise is described.

Case Reports

Case 1

A 38-year-old male had acute rheumatic fever with carditis in 1945. Excretional dyspnea began in 1961 and acute congestive heart failure in 1964. The predominant valvular lesion was aortic insufficiency. A Starr-Edwards aortic valve prothesis was inserted in September 1964. Postoperatively, the patient did well except for complaints of recurrent anterior chest pain. No diastolic murmur was present. His laboratory evaluation was completely normal, including hemoglobin and reticulocyte count.

In August 1965 he was evaluated for "cardiac neurosis." The physical findings were unremarkable other than for a Grade 3/6 precordial systolic murmur with a characteristic prosthetic "click." No diastolic murmur was heard. There was no hepatosplenomegaly or findings of congestive heart failure. The hemoglobin was 14.5 g/100 ml. Special hematological studies indicated chronic hemolysis (Table).

Case 2

In 1958 a 42-year-old male farmer was found to have a cardiac murmur of aortic stenosis on evaluation of exertional chest pain. There was no history of rheumatic fever. In October 1964, despite prior restriction of activity, he began to have severe orthopnea, exertional dyspnea, palpitations and syncopal episodes. In January 1965 cardiac catheterization studies confirmed the presence of aortic valvular stenosis (a systolic gradient of 60 mm of mercury) with minimal regurgitation. A Starr-Edwards aortic valve prosthesis was inserted on March 10, 1965. The postoperative course was uneventful. No diastolic murmur was initially described. Preoperatively the hemoglobin was 16.1 g/100 ml. Five blood transfusions were given following surgery to raise the low postoperative hemoglobin. Four weeks after the operation, the hemoglobin was 11.9 g/100 ml; the reticulocyte count, 10.5 percent.

---

*Department of Medicine, Veterans Administration Hospital and the University of Minnesota Medical School, Minneapolis, Minnesota.

Fourteen weeks after the operation the patient complained of increasing fatigue, shortness of breath, and "pounding" in his chest with the slightest exertion; and his urine was persistently dark. Physical examination revealed pallor. A grade 3/6 precordial systolic murmur with a prosthetic "click," and a grade 2/6 mid-diastolic murmur along the left sternal border were noted. The latter was thought to represent aortic regurgitation. Cardiomegaly, a palpable thrill over the aortic area, and a wide pulse pressure were also present. The hemoglobin was 6.7 g/100 ml and the reticulocyte count, 6 percent. Oral iron therapy was instituted and continued until May 1966, but anemia persisted because of continuing hemolysis. At this time he was again hospitalized for the severe anemia and refractory congestive heart failure.

The patient was readmitted to the hospital in March 1967 because of progressive weakness, loss of appetite, easy fatigability and persistence of dark urine. (Hematological evaluation indicated a severe hemolysis (Table). Demonstration of aortic insufficiency clinically and by angiography was the indication for surgical repair of the leak around the prosthetic aortic valve. The leak was due to prosthetic cuff separation in the area below the left coronary artery near the sinus of Valsalva. This was repaired with a 2-0 Tevdek suture and Ivalon sponge. The patient's postoperative course was uneventful. A postoperative hemoglobin was 13.6 g/100 ml. One year after surgery a compensated hemolytic state was documented. The hemoglobin was 14.0 g/100 ml, and multiple reticulocyte counts averaged 4.5 percent.

Results

A summary of the hematological data on the two patients, as well as a comparison with similar data reported by Sears and Crosby[8] in 1965, is found in the Table. A majority of the tests were abnormal for Patient 2.

Increased Fragmented Red Cells

The hemolytic process is characterized by an increased number of fragmented red blood cells in the peripheral smear. Reticulocytosis was present to a significant degree and haptoglobins were absent. Methemoglobinemia indicates red blood cell destruction and overloading of the haptoglobin system. Excess iron was present in the urine. Both direct and indirect Coombs' tests were negative.

Shortened Survival Time of Red Cells

Even though iron was being lost in the urine, the serum iron was normal, as was the iron-binding capacity. Bone-marrow iron, a more sensitive measurement of body iron stores, reflected the urinary iron loss. Fecal urobilinogen from red blood cell destruction was elevated. Chromium^{51}-tagged red blood cells from the patient and from a normal healthy donor showed shortened survival times indicating an extra corpuscular mechanism of cell destruction. Bone marrow examination showed increased erythroid activity.

Patient 1, who was thought to be asymptomatic, did in fact have a mild though compensated process characterized by reticulocytosis, absent haptoglobins and increased urinary heme pigments. These observations point to an extra corpuscular mechanism in the production of the anemia. This process was accentuated by exercise and was associated with significant iron loss.

Patient 2, who was symptomatic, had definite evidence of erythrocyte destruction by an extra-corpuscular mechanism. This hemolysis was characterized by increased reticulocytes, presence of fragmented red blood cells in the peripheral smear, methemalbuminemia, absent haptoglobins, increased fecal urobilinogens, hemosiderinuria, and markedly shortened red blood cell T/2 survival time.

Other Factors

In a 1965 report by Sears and Crosby,[8] hemolysis with anemia appeared in one patient after repair of an ostium primum defect and in another, following replacement of a damaged aortic valve with a Starr-Edwards prosthesis (Table). Their first patient had a striking pattern of diurnal hemoglobinuria; their second patient showed a relationship between physical activity and rate of hemolysis.

In an attempt to show this relationship in our patients, each was exercised by walking down six flights of stairs. Measurement of plasma heme pigments before and after exercise, as seen in the Table, showed an elevated resting level and a significant increase with exertion in Patient 2. Though there was measurable urinary hemoglobin in both patients, indicating increased hemoglobin excretion, there was no significant day/night variation.

Discussion

Hemolytic anemia following the insertion of an intracardiac prosthesis was first reported in 1955 by Sarnoff and Case.[9] Severe hemolytic anemia developed in dogs following the insertion of a Hufnagel valve into the thoracic aorta. The anemia was characterized by hemoglobinemia, hemoglobinuria, hemosiderinuria and a greatly shortened red blood cell survival time. The hemolytic process apparently resulted from mechanical trauma to the red cells when the rigid ball was forced against the rigid housing. When an elastic silicone valve with a more resilient housing was used, a substantial reduction in red cell destruction was noted.

Hemolytic anemia, as a complication of an intracardiac prosthesis, was first described by Sayed and his associates in 1961.[1] A patient, with an ostium-primum defect repaired with a teflon patch, developed anemia, reticulocytosis, hemoglobinemia, methemalbuminemia and fragmented red blood cells postoperatively. Studies of this patient suggested that the hemolysis resulted from mechanical conditions in the heart, presumably from a regurgitant jet of blood through the cleft mitral valve being driven against the bare teflon patch. The cleft in the valve was repaired and the patch covered with endothelium at surgery. The hemolytic anemia disappeared. Whether the presence of the teflon alone, the lack of an endothelial covering over a roughened surface, or the turbulence of the blood caused the hemolysis could not be determined. Possibly all three factors were involved.

Additional reports of hemolysis associated with patch repair of septal and atrioventricular canal defects came from Verdon and associates and from Sigler and his co-workers in 1963.[2,3] In each patient an iron deficiency developed, probably related to the continued hemoglobinuria. In each individual, a persistent defect in the mitral valve permitted a jet of blood to strike the bare side of the teflon patch. Correction of the defect resulted in abrupt cessation of hemolysis.

Sanyl and his group, in 1964, described a case of hemolytic anemia following closure of an ostium-primum defect.[4] They were able to

maintain their patient in a compensated state by blood transfusions and iron replacement. These authors felt that vigorous medical management was indicated because of the high mortality associated with reoperation.

Hemolytic anemia following insertion of a Starr-Edwards ball valve was first reported by Stevenson and Baker[5] and by Marsh,[6] in 1964. Four patients developed a hemolytic anemia after insertion of a Starr-Edwards valve for correction of aortic valvular disease. In these cases, the postoperative course was complicated by aortic insufficiency. These writers concluded that recognition of hemolytic anemia following prosthetic valve surgery was important because it indicated the operation had not been completely successful.

Reed and Dunn in 1964 demonstrated that aortic insufficiency alone was not a requisite in the development of hemolytic anemia.[10] At necropsy their patient did not have any anatomical evidence of aortic insufficiency; instead, there was obstruction to blood flow in the aorta during systole when the ball was in the open portion of the cage. This allowed little clearance around the ball, and the resultant turbulence was probably a major factor in hemolysis.

In a somewhat similar patient described by Garcia et al. severe hemolytic anemia developed in the absence of aortic valve insufficiency, over a two-year period following surgery,[11] and could not be controlled by medical management. The prosthesis was therefore replaced by a homograft aortic valve. The silastic ball component of the Starr-Edwards valve was found to be enlarged, roughened, and coated with lipids, thus obstructing blood flow through the valve. This enlargement resulted in restriction of free movement of the ball within its cage and probably led directly to the mechanical hemolytic anemia. Several months after the insertion of the homograft valve the patient had normal blood parameters, as well as return of cardiac function to a near normal state.

Certain diagnostic tests are important to detect hemolysis in a patient following cardiac surgery. The peripheral blood smear will show fragments of red blood cells, poikilocytosis, and anisocytosis and polychromasia. The red blood cells may also reflect chronic iron deficiency. The hemoglobin and hematocrit will be correspondingly low. The reticulocyte count will be elevated, even in the face of a normal or near-normal hemoglobin. The detection of hemosiderin in the urine is important in documenting chronic iron loss. Plasma haptoglobins are absent and plasma hemoglobin is increased. The presence of methemalbumin in the serum is diagnostic of a hemolytic process, as is the presence of increased fecal urobilinogen. Measurement of serum iron and iron-binding capacity may frequently reflect the chronic iron loss.

The evaluation of iron in the bone marrow is a more sensitive measurement of reduced body iron stores. These stores may be decreased when the serum iron is still within a normal range. The number of normoblasts in the bone marrow, reflecting erythroid hyperplasia, should also be noted. Both the direct and indirect Coombs' are usually negative except for those rare instances of "auto-immune" hemolytic anemia, an example of which was reported by Pirofsky et al.[7] Measurement of chromium^{51}-tagged red blood cell T/2 survival time will show a decrease in the patient's own cells as well as in normal donor cells circulating in the patient. Body scanning for sequestration of labelled red blood cells is usually not helpful. In cases where this has been done, there has been no selective sequestration in the liver or spleen. Measurements of osmotic and mechanical fragility are usually normal, as are tests for antibodies, including cold agglutinins, cold hemolysins, and acid hemolysins. Hemoglobin electrophoresis and red blood cell metabolic studies have been similarly normal or negative.

Conservative management is usually the best initial approach with these patients. Successful compensation has been reported with the use of multiple transfusions, steroids, iron replacement and, in one instance, auto-transfusion. The possible value of limitation of physical activity should be considered in some patients. Uncompensated hemolytic anemia, alone, or associated with persistent valve insufficiency or recurrent left to right shunt, may be an indication for reoperation.

Summary

Chronic hemolysis was documented in two patients with Starr-Edwards aortic valve prostheses. Diagnosis was suspected from find-

ings of fragmented red blood cells in the peripheral smear and an increase in the number of reticulocytes. The process was further demonstrated by a shortened chromium^{51} T/2 survival time, decreased serum haptoglobins, increased plasma heme pigments and increased urinary hemosiderin excretion. The process was accentuated by exercise and associated with significant iron loss.

Conservative management in symptomatic patients may require transfusions, iron replacement, and restriction of physical exercise. Persistence of an uncompensated anemia is often an indication for reoperation.

Acknowledgments

We are indebted to Donna H. Ripley, Special Hematologist, Special Hematology Laboratory and Marija B. Feders, Research Technologist, Minneapolis Veterans Administration Hospital, for the special hematology studies on these patients.

Medicine in the Middle Ages

Mention should also be made of that famous medieval surgeon, Guy de Chauliac, who studied medicine at Toulouse, Montpellier, Paris, and Bologna—a record that should encourage students who don't make it the first time. He was immensely learned, especially about medical schools. The most memorable thing about Guy is his having been probably the first to employ traction in the treatment of a fracture. Anyone with a broken thigh who has been ingeniously trussed up with ropes, pulleys, and weights until he looks like a spider weaving a web should thank Guy de Chauliac and not Rube Goldberg.*

Worry

There are two days in every week about which we should not worry. One is yesterday, with its mistakes and cares, its aches and pains. Yesterday has passed forever beyond our control.

The other day is tomorrow, with its possible adversities and blunders. Until its sun rises we have no stake in tomorrow, for it is as yet unborn.

That leaves only one day—today. Any man can fight the battle of just one day. It is only when we add the burden of those two awful eternities—yesterday and tomorrow—that we are liable to break down.*

FEATURE SPECIAL

Medical Terms and Their Lay Synonyms

Eugene F. Binet, M.D.
Syracuse, New York

There is no doubt that scientific nomenclature has its advantages. It predisposes to exactness and usually pinpoints objects with remarkable accuracy. Its preciseness requires that the user understand it as well as the listener. This language is supposedly only denotative, but through common usage has taken on a connotative value within the scientific professions.

Unfortunately, to the average man scientific language is but a conglomeration of Latin and Greek endings preceded by even more weird beginnings. This is perhaps most notable in medical jargon where the doctor's vocabulary consists of "oses" and "itises" and the patient speaks of aches and pains. This is fine when patients talk to patients and physicians consult among themselves; but when doctor and patient meet there are usually, if not always, problems of communication. In most cases these are resolved by repeated questioning and constant probing by the doctor into the patient's complaints—to the point of sheer boredom and needless repetition. In some instances the doctor never learns what the patient's problems are; in other cases the patient tells the doctor what he wants to know regardless of its bearing on the truth. These two consequences are certainly anything but satisfactory.

It goes without saying that the problems of communication ever present between physician and patient deserve resolution. As it would be quite impossible to teach the myriad of lay people the meanings of medical expressions and how and when to use them, it behooves us doctors to learn, appreciate, and understand those expressions, those disease names, those conditions, those flagrantly false and nonsensical terms patients use.

Included here is such a list.

The list is certainly not comprehensive but is, however, fairly accurate. Some of the definitions appear contradictory, others incomprehensible; many of the terms are obsolete, others quite up-to-date. Most of them are American if not English. Some you have used yourself. Others you will never see again.

These 1500 words are just the beginning of a list that has no ending, for people are always devising new ways to describe things. It is impossible to learn them all, but it would be nice to know a few of them. Besides they make great fodder for one-upmanship!

Anesthesia after Myocardial Infarction

SAIT TARHAN, M.D.*
EMERSON A. MOFFITT, M.D.*
Rochester, Minnesota

Arteriosclerosis of the coronary arteries is the leading cause of death in this country. According to a national health study, 2.8% of all adult males between 18 and 70 years have coronary heart disease, and an additional 2.5% are suspected of having it.[1] This survey also revealed that 23.6% of all men who have angina pectoris have had myocardial infarction. As a result, the number of patients with coronary artery disease undergoing some form of surgery is increasing steadily. These patients present problems related to the specific physiologic changes caused by their pathologic condition. A special group consists of those patients who must be subjected to the stress of anesthesia and operation during the early postinfarction period, with a resulting higher mortality rate.[2]

The Surgical Risk

Optimal Time

The optimal time to operate on a patient who has had myocardial infarction is by far the most important facet of this problem. Usually healing is complete within three months, depending on the size of the infarct and the condition of the myocardial circulation.[3] Most infarcts require about two months to establish vascularized scar tissue and perhaps another month to consolidate the recovery. Thus the extremely critical period probably extends over two months. This concept is supported by statistical data. In a study by Arkins and associates,[2] among 27 patients with recent infarction (less than three months), 11 died during or after operation (40%); yet, in a group with old myocardial infarction (more than three months), only 54 of 240 patients died (22%).

High Mortality

In a study by Fraser and associates,[4] the overall mortality rate was 38% for patients with recent infarction and particularly high for patients who underwent operation within 15 days after myocardial infarction. Of 28 patients operated on during this interval, 12 died (43%).[4] However, only six of these deaths were related to the cardiac disease. Associated diseases that necessitated operation were considered the direct cause of the other deaths. The mortality rate decreased for those operated on after 15 days. The impression was that judicious delay of operation in all but the most urgent situations was indicated during this period because prognosis seemed to be better if operation took place after the first 15 days.

---

*Mayo Clinic and Mayo Foundation: Section of Anesthesiology.

Location of the Infarct

The type of infarction was also found to be significantly related to the outcome. In the study of Arkins and co-workers,[2] 13 patients had recent anterior and posterior wall infarction (transmural) and 14, subendocardial infarction. Ten of the 13 with transmural infarction died, but only one with a subendocardial lesion died. According to this study, there was no significant difference after operation between the mortality rate of patients with old infarction and those with other coronary changes without infarction (mortality rates of 22% versus 21%).

Location of the myocardial infarct is of special interest to the anesthesiologist, especially during operation. Anterior infarcts result from occlusion of the anterior descending branch of the left coronary artery.[5] Because this artery does not supply the sino-atrial or the atrioventricular node, heart block is uncommon. Hence, rhythm and conduction defects are unlikely with anterior infarction; yet an extensive infarct may cause congestive heart failure. Lateral infarction results from occlusion of the left circumflex coronary artery,[5] which has a variable distribution. If the sinoatrial node or the atrioventricular node is supplied by this artery, serious arrhythmias or heart block can be expected. A posterior infarct results from occlusion of the right coronary artery,[5] which regularly supplies both of these types of nodes, and these patients are most likely to have disturbances of rate and rhythm.

Preoperative Considerations

The aim of any anesthetic technique is to provide a state in which the surgeon can operate with as little physiologic and emotional trauma to the patient as possible.[6] In this respect, anesthesia for the patient with cardiac disease is not different in kind but only in degree.

Cardiac Stability

It is important to determine the state of cardiac reserve and the stability of the cardiac status. A careful history, physical examination, and preoperative electrocardiogram should identify the presence of previous myocardial infarction or coronary insufficiency. It is also important to make sure that the changes are not due to a recent infarction. If the infarct is recent, elective surgery should be postponed as long as possible, preferably beyond the three-month healing period.

Patients with signs of coronary insufficiency, cardiac enlargement, congestive heart failure, cardiac arrhythmias, or pulmonary diseases should be adequately prepared before operation by appropriate medical treatment. This ensures that the patient is brought to the operating room with the best possible cardiac compensation.[7]

Prophylactic Digitalization

Preoperative preparation should include prophylactic digitalization in patients who have cardiac failure or impaired reserve, treatment of anemia by proper measures, and regulation of fluid and electrolyte balance. In patients who have been receiving prolonged digitalis and diuretic therapy, total-body potassium is likely to be reduced; that is, a significant reduction of intracellular potassium may be present without a change in the serum potassium level and may cause hyperirritability of the myocardium, with ventricular ectopic rhythms.[6] One rational treatment is to give potassium chloride intravenously; another is to depress the ectopic foci with diphenylhydantoin or lidocaine.

Sedation

Tachycardia of emotional origin should be avoided by reassurance and adequate sedation.

Effective doses of sedative drugs are safe and most worthwhile to relieve the anxiety of the patient who is to undergo operation. Morphine has a specific place because it has a calming effect, may relieve the pulmonary congestion by allowing peripheral pooling,[8] and may improve ventricular performance.[9] Belladonna drugs given before operation may prevent vagal bradycardia, but if this occurs it can be treated effectively by small intravenous doses of atropine when needed. Another effective drug for premedication is meperidine. The small decrease in arterial oxygen tension that is seen when this drug[10] is used also occurs after morphine, but the decrease can be easily counteracted with an increase of inspired oxygen tension.

Considerations During Operation

The principles are: (1) maintaining light anesthesia, (2) assuring satisfactory ventilation (usually by controlling it) with adequate oxygenation, (3) abolishing vagal stimulation, and (4) avoiding serious arrhythmias and hypotension. Our experience is that the patient with impaired circulatory system tolerates even less depression than does the patient without such impairment. Thus all efforts are directed at maintaining the circulation. Fortunately, the cardiac patient who can tolerate only a light level of anesthesia usually needs no more than that. Equally important is the realization that the patient with an extremely low cardiac output can maintain a reasonably stable blood pressure if given light anesthesia with ample oxygen.[6] As is true in so many circumstances, it does not matter what you use but how well you use it. The choice of anesthesia depends on one's preference and experience in relation to what is safest for the patient's condition.

Almost every anesthetic agent has a depressant effect on the myocardium in deeper levels that decreases cardiac output. The myocardial depressant effect of halothane is well tolerated in light levels of anesthesia.[11] Hypoxia and especially hypercapnia have an important part in the initiation of arrhythmias. In general, hypoxia does not often cause arrhythmia in the normal heart; but if the patient has coronary heart disease, ventricular arrhythmias easily result because of enhanced excitability of the hypoxic areas of the heart muscle.[12] Hypercapnia also provokes ectopic rhythms.

Ventilation

It has been established clinically that retention of carbon dioxide during halothane anesthesia causes various arrhythmias of ventricular origin.[12] Hypoxia can be due to laryngeal spasm, hypoventilation, ventilation-perfusion abnormalities, and pulmonary shunting (which occurs particularly during thoracic surgery). Arterial oxygen tension can decrease to dangerously low levels even when the patient is ventilated with 100% oxygen, because of pulmonary shunting.[13]

Hypotension

Avoiding a decrease in blood pressure probably is the most important single factor in the safety of the patient during operation. If a decrease does occur, the cause should be determined and treatment given immediately. Hypotension will cause a reduction in coronary blood flow, leading in turn to myocardial hypoxia, with reduced cardiac output and further decrease in blood pressure.[14] Therefore the importance of detecting even transitory bouts of hypotension is apparent.

Monitoring

Since the prompt recognition of changes during anesthesia is critical for the patient's prognosis, monitoring of several variables is mandatory. This includes the use of the electrocardiogram and the monitoring of the heart rate and tones by stethoscope and of the blood pressure by cuff or even by direct reading with a pressure transducer. Also the capability to do serial analyses for oxygen, acid-base balance, and electrolytes during or after operation for these high-risk patients adds greatly to the safety of the procedure.

Postoperative Considerations

The incidence of myocardial infarction after operation is probably higher than is generally suspected. Arkins and associates[2] reported that 5% of the 1,005 patients with coronary artery disease had myocardial infarction after operation. Patients with recent myocardial infarction are exposed to a greater risk of recurrent infarction,[7] and the mortality rate for patients with recurrent infarctions is high. In one series, three patients who had recent infarction before operation died from recurrent postoperative infarction. In the same study, 18 patients with old myocardial infarcts also had recurrent postoperative infarcts, and 14 died (77.7%).[2]

Hemodynamic disturbances such as tachycardia, hypotension, and lowered cardiac output are the responsible factors for the infarct.[7] Hypoxemia also occurs to some degree after general anesthesia and every operation. Arterial oxygen tension decreases on the second and third postoperative days, when the patient is breathing air, because of miliary atelectasis.[15] This period of hypoxemia corresponds well with the occurrence of more than half of the observed myocardial infarcts during the first three postoperative days.[7] The finding that all patients, not only those with heart disease, require treatment of lowered arterial oxygen tension needs wider appreciation by those involved in anesthesia and surgery. A corollary here is the necessity for giving oxygen to patients after operation and for making vigorous efforts to reduce atelectasis, such as encouraging frequent coughing and deep breathing and turning the patient, as well as the use of intermittent positive-pressure breathing.

Summary

The mortality rate for patients with recent myocardial infarction is high if they are submitted to the stress of anesthesia and surgery. Elective surgery should be delayed until after a healing period of three months. Patients should be prepared and brought to surgery in the best possible state of cardiac compensation. Management of the patient during the operation includes a light level of anesthesia, adequately controlled ventilation and oxygenation, and abolition of undesirable vagal reflexes. Monitoring must be sufficient to provide adequate knowledge of the dynamic status of the patient. Hemodynamics must be carefully observed and corrected or supported as needed.

Postoperative myocardial infarction is frequent and is associated with a high mortality rate. Patients with coronary artery disease should be kept under constant surveillance after the operation. Hypoxemia commonly occurs after anesthesia, requiring treatment with oxygen and vigorous efforts to reduce atelectasis.

Hepatic Coma in Pregnancy

Treated with Exchange Transfusion

ARNOLD W. LINDALL, M.D., Ph.D.*
DONALD MASON, M.D.*
ALVIN L. SCHULTZ, M.D.*
Minneapolis, Minnesota

There have now been about 82 cases of fulminant hepatic coma secondary to infectious hepatitis and other causes treated by exchange transfusion.[1] Since the evaluation of this treatment is still in its early stages, we felt it was necessary to include another case in the literature. This case also is unique in that the subject was a young pregnant female. There has been one other pregnant woman with hepatic failure successfully treated by exchange transfusion.[2] The diagnosis of this reported case was fatty change of the liver associated with the third trimester of pregnancy.

Report of a Case

History and Physical Examination

An 18-year-old white female was admitted to the obstetrical service after the abrupt onset of nausea, vomiting and abnormal pain three days prior to admission. She was 20 weeks pregnant. Four days prior to admission she had seen her private doctor, who diagnosed a urinary tract infection and started her on methenamine mandelate (Mandilamine) and phenazopyridine hydrochloride (Pyridium). Associated with this medication, her urine became orange in color. She was also taking an iron and vitamin preparation. There was no history of blood transfusions, tranquilizing drugs, tetracycline or infectious hepatitis. No history of exposure to narcotics, amphetamines or methadrine was elicited. Past medical history included one previous pregnancy terminating in a live birth and accompanied by an episode of cervicitis.

Physical Findings

Physical examination revealed an icteric, somewhat drowsy female who responded appropriately to questions. Other positive findings included nystagmus to all quadrants and a moderately loud systolic murmur at the left sternal border. The liver edge was at the costal margin and tender. The uterine fundus was at the level of the umbilicus. No other neurological abnormalities were observed.

Laboratory Data

Initial laboratory studies found a hemoglobin of 12.8 Gm%, a white blood count of 18,200 with 84% neutrophils. Urinalysis showed 1+ albuminuria and 10-12 wbc/hpf. The prothrombin time was 39.2 seconds with a control of 12.6. The initial SGOT was over 250 units but, unfortunately, the serum was not diluted. The following day the SGOT was greater than 750 units, and again dilutions were not carried out to yield the exact value. The total bilirubin was 10.2 mg% with 44% direct-acting. The alkaline phosphatase was 29 King-Armstrong units. The CO_2 was 9 mEq/L while the other serum electrolytes were normal. A cephalin flocculation was 4+ and thymol turbidity 20 units. A lumbar puncture was traumatic but otherwise negative. The tentative diagnosis of infectious hepatitis was made.

---

*Department of Internal Medicine, Hennepin County General Hospital, Minneapolis.

Hospital Course

On the evening of admission the patient was treated with parenteral vitamin K, 5% dextrose solution containing sodium bicarbonate, potassium and sodium chloride; penicillin and chloramphenicol (chloromycetin) were also administered. Twelve hours after admission she became restless and by eighteen hours after admission she had become comatose. Neurological examination showed dysconjugate gaze, pupils midposition and reactive to light, decerebrate rigidity with positive Babinski reflexes. Conjunctival hemorrhages were present. A carotid angiogram was negative.

Exchange Transfusion

Based on the presumptive diagnosis of fulminant hepatic coma secondary to infectious hepatitis it was elected to perform an exchange transfusion. Ten units of citrated blood, less than five days old, were exchanged. Twelve hours following the first exchange transfusion the decerebrate posturing had disappeared. Two more exchange transfusions were done 48 and 72 hours after the first exchange. In the latter procedures nine and ten units of freshly-drawn heparinized blood were used respectively. Twelve hours after the last exchange transfusion, the patient began to respond and by 24 hours she was entirely awake. During the period of coma, hydrocortisone sodium succinate (Solu-Cortef) was continuously administered up to a dose of 1.0 Gm. per day. Neomycin sulfate was administered by means of a nasogastric tube following tap water enemas.

Further treatment following the period of coma included prednisone 30 mg. per day in divided doses, which was continued and finally tapered and discontinued on the 50th hospital day. A high caloric diet with slowly increasing protein was administered. On the day she became conscious she began to show a pneumonitis with staphylococcus and pseudomonas, which was treated with sodium cephalothin (Keflin) and sodium colistimethate (Coly-Mycin). On the 21st hospital day she aborted an 800-Gm. fetus which had been alive right up to the delivery.

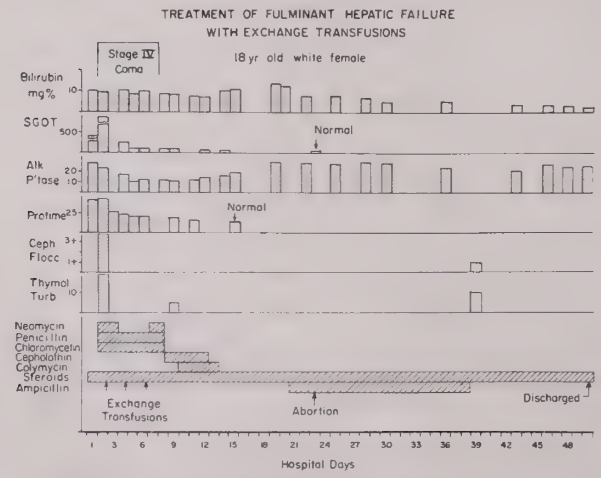

Fig. 1—The pertinent laboratory values during the hospital course of a young pregnant female with fulminant hepatic failure.

Summary of the pertinent laboratory results during the hospitalization appears in Figure 1.

Pathology

Liver biopsies were done on the ninth and 46th hospital day. The first specimen showed marked bile plugging of canaliculi, bile stasis, ballooning degeneration and areas of pericholangitic inflammation with polymorphonuclear infiltration (Figures 2 and 3). The later specimen showed bile thrombi in the canaliculi and partial resolution of the earlier changes (Figure 4). The changes seen in the biopsy were not entirely typical of infectious hepatitis; however, the effect of the pregnancy and the

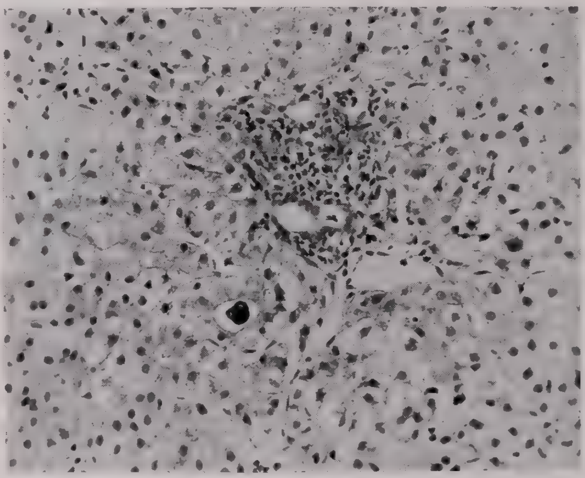

Fig. 2—A liver biopsy specimen from the ninth hospital day of a 18-year-old female with fulminant hepatic failure. Bile stasis and acute pericholangitis can be seen. Magnification 240x.

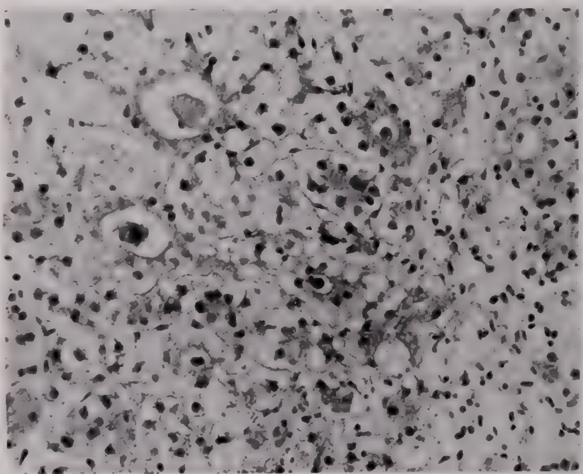

Fig. 3—Another area from the first liver biopsy with ballooning degeneration and demonstrating disordered architecture. Magnification 240x.

large doses of steroids on the liver must be taken into account in interpreting the microscopic changes. Considering all the data, the most likely diagnosis would seem to be viral hepatitis. The architecture of the aborted fetus liver was normal. The patient was discharged after 50 days of hospitalization. She is well five months later.

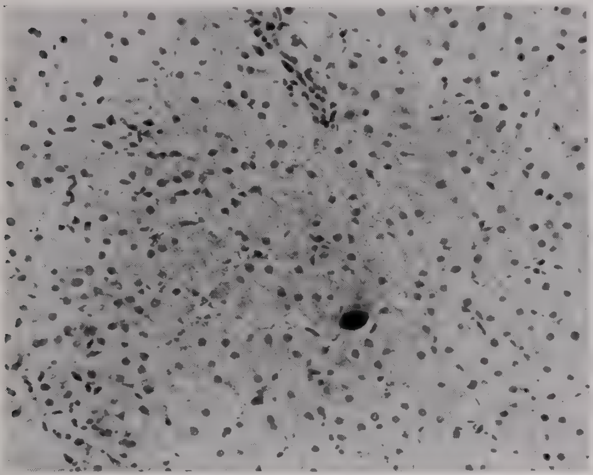

Fig. 4—A repeat liver biopsy specimen on the 46th hospital day showing residual bile plugging and improvement. Magnification 240x.

Discussion

The cause of the fulminant hepatic failure in this case was not entirely clear since the liver biopsies did not indicate the usual pattern of parenchymal cell necrosis seen in infectious hepatitis. However, the structural picture, mostly of the cholestatic type, may have been remarkably altered by massive steroid therapy and pregnancy.

Recurrent jaundice of pregnancy would seem to be an unlikely etiology in this case. In a series of Danish patients with jaundice in pregnancy, 75% of the cases were said to be recurrent jaundice of pregnancy, while 17% were viral hepatitis.[3] The abnormal cephalin flocculation, thymol turbidity, and bilirubin levels in our patient are not consistent with this diagnosis.[4] The thymol turbidity is generally normal in recurrent jaundice of pregnancy, while bilirubin is said not to be a greater than 8 mg %. Viral hepatitis in pregnancy has been reported in India to have an extremely grave prognosis.[5] Western authors do not indicate such a high mortality[4] and attribute the Indian result to poor nutrition.

The first series of patients treated by exchange transfusion were those of Trey et al.[6] There have since been about 80 cases treated in this fashion[1] and some modifications have been presented, such as the use of plasma exchange.[7]

The survival in this case of fulminant liver failure was unexpected, and one would like to attribute it to the vigorous treatment. However, there were three modes of therapy combined: standard hepatic coma therapy, steroids, and exchange transfusion. It is therefore not possible to consider this case solely as evidence supporting the value of exchange transfusion. In a recent report Davis et al.[8] indicated that exchange transfusion was no better than conventional treatment in cases of fulminant viral hepatitis. In their series 37% of 16 patients survived with conventional therapy including steroids. Of the six survivors two are described as having decerebrate rigidity during the coma period.

In contrast to the remarkable recovery rate of Davis, only 17.4% of 207 cases reported in the literature from 1951 to 1967 and summarized by Burnell et al.[9] survived massive hepatic necrosis after viral hepatitis with conventional treatment and steroids. These authors collected their cases from 14 separate reported series ranging from two to 26 cases each. If one computes the standard deviation of these series using a weighting factor* to emphasize the larger series one discovers that one standard deviation (18.6%) would encompass the range 0% to 36% recovery. One cannot then conclude from one small series the efficacy or failure of treatment. Obviously many more cases are needed. More recently a cooperative study report shows about a 22% survival in all cases of fulminant hepatic failure compared to 10% in the non-exchange group.[1] This study had, at the time of the report, 150 individuals; however, the difference between those exchanged and not exchanged was not statistically significant.

Summary

A pregnant woman with fulminant hepatic failure was successfully treated by exchange transfusion coupled with conventional measures.

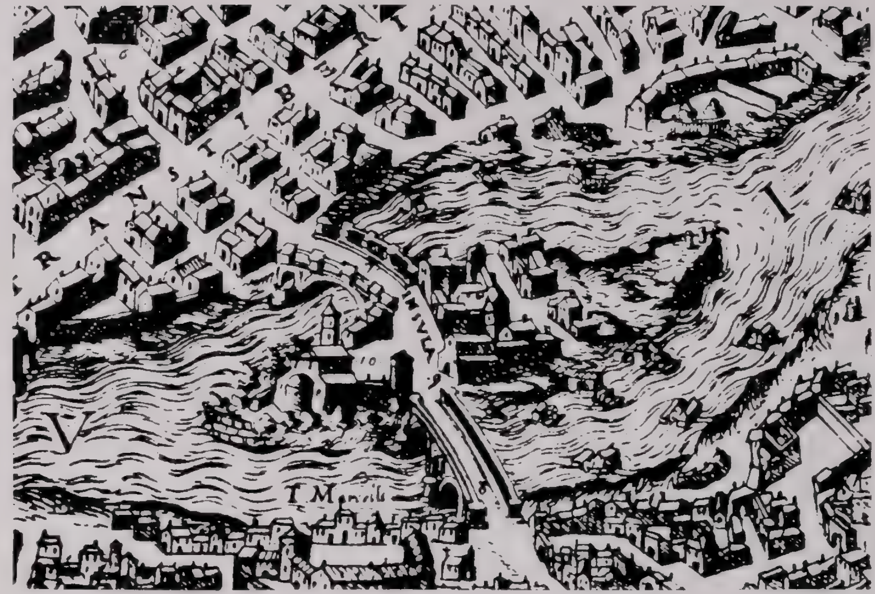
FEATURE SPECIAL

Old Hospitals



The Ship in the Tiber from an engraving dated 1577

The Ship of Aesculapius

During an epidemic about 293 B.C., the Romans adopted the Greek god of medicine, Aesculapius, as one of their major deities, and they erected to him a great temple on this island in the Tiber. They imported physicians and Aesculapian serpents from the great Greek medical center at Epidaurus, and made the island the chief hospital or sanitarium of the city. The island, cut into the shape of a ship 300 yards in length, 80 yards in beam and complete with mast, prow and stern, resembled a huge ship at anchor in the river. Beside the great temple, the island provided smaller satellite temples, shelters for the sick, medicinal baths, and enterprising Romans selling votive offerings on the river bank. During times of pestilence, the location of the medical center on an island provided at least a rudiment of isolation.

Imperial Rome saw the island become a refuge for the sick poor where some men left their ill or worn-out slaves to avoid the trouble of caring for them. The Emperor Claudius (A.D. 41-54) decreed that slaves recovering their health on the island should henceforth be free.

With the coming of the Christian era, the dedication of the island changed, but not the function. A hospice dedicated to St. Bartholomew was built about 1100 A.D., and the Hospital of St. John Calibita in 1575. The latter, now more popularly known as Ospedale Fatebenefratelli, still thrives as a modern 280-bed voluntary hospital.

The island is probably the oldest medical center in the world. Some of the columns which support the Basilica of St. Bartholomew today are said to be part of the original Aesculapian Temple, and down near the island's "stern" one can still make out an Aesculapian staff and serpent carved into the rock by the ancient Romans.

Coronary Care*

In the Very Small Hospital

JOHN W. ANDERSON, M.D.†
Blue Earth, Minnesota

Aggressive management of patients who have suffered an acute myocardial infarction has been well accepted in the large and medium-sized hospitals.[1-4] The very small rural hospitals, however, have not been as quick to accept the challenge, but an occasional very small hospital has overcome the obstacle of smallness, recognizing the importance of immediately available facilities and personnel as contrasted to the risks of transporting an acute myocardial infarction patient long distances to larger centers.[5]

Organization

Plans for establishing an intensive coronary care unit were initiated at the United Hospital in Blue Earth, Minnesota, in early 1967. The hospital is a 40-bed general community hospital serving the city of 4,000 population and the surrounding farm area of 10,000 population. The hospital has a 15-bed satellite unit in the city of Winnebago 12 miles away. The combined staff of the two hospitals is composed of eight private practitioners, all generalists. The radiology and laboratory departments are headed by a visiting radiologist and a visiting pathologist. The staff agreed to the desirability of an intensive coronary care unit and further agreed to admit all patients to the unit with proved or suspected acute myocardial infarction. One member of the staff accepted the responsibility of organizing and operating the unit. A committee was formed to include the physician in charge, the hospital administrator and the director of nursing.

It was recognized that the success of the unit would depend on the competence of the nursing staff; therefore a course of instruction was conducted by the physician in charge, and by visiting physicians and nurses from

the Mayo Clinic and St. Mary's Hospital of Rochester, Minnesota. Emphasis throughout the course was placed on prevention of cardiac arrest rather than treatment.

Equipment

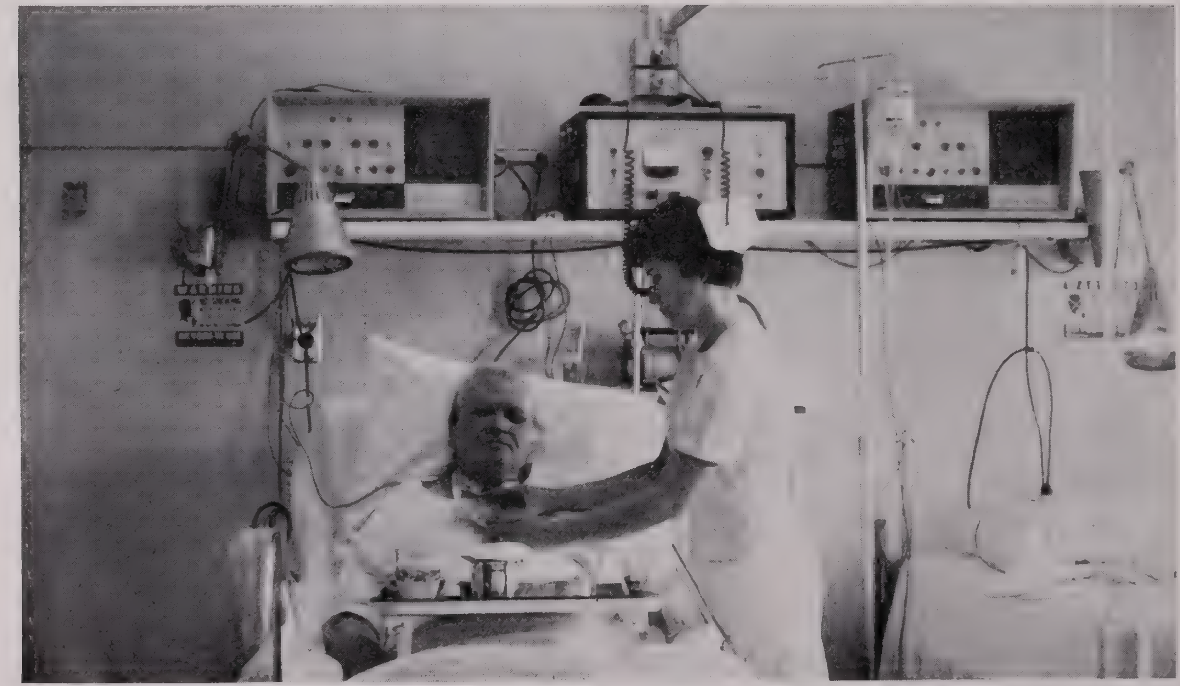
A private room with bath located next to the nursing station was converted to a two-bed unit. A portion of the wall between the room and the nursing station was cut out and replaced with sliding glass to allow constant visual and auditory contact between the station and the patients in the unit. Oxygen was piped into the unit. Each bed had its own overhead monitor-pacer unit. One defibrillator was mounted overhead between the two beds. A remote unit at the nursing station contained two scopes, two rate meters, automatic recording equipment and alarms. Each bed had its own high intensity light source. A third monitor-pacer unit and a second defibrillator were mounted on a portable stand to be kept in the operating room. This portable unit was moved to the x-ray department during insertion of transvenous electrodes and served as a standby unit for use anywhere in the hospital. A small battery-operated portable demand pacer was also available in the unit for transporting and ambulating patients requiring artificial pacing.

Unit Usage and Policy

The unit was designed to provide priority care for patients with acute myocardial ischemia with or without infarction, patients with cardiac mechanism failure or patients with severe congestive failure. However, it was also planned to serve any patient who was critically but not hopelessly ill or injured, including patients in shock or vascular collapse from any cause, including blood loss from severe injury, gastrointestinal and obstetrical hemorrhage.[6] This also included patients with diabetic acidosis, major electrolyte abnormalities, crushing injuries of the chest with myocardial injury or tracheostomies, postoperative patients with critical problems and many other acute problems. Patients in the following categories were excluded from the unit: hopelessly ill, acute alcoholism, psychosis with management problems or ill with communicable diseases.

Patient Management

An intravenous infusion of 5% dextrose and water was started immediately on each new patient. Each patient was then connected to



Figure—Intensive coronary care unit—Blue Earth United Hospital the monitor-pacer by chest electrodes. Oxygen was given to all patients by mask or nasal catheter for at least three days. A list of 32 routine admission orders was used as a check list by the nurse in charge. A reference manual of standard treatment procedures was prepared by the physician in charge and kept in the unit as a guide for the nurses and physicians, to avoid any hesitancy in the treatment of arrhythmias or other complications. In most instances dilute solutions of lidocaine and isoproterenol were connected to the intravenous infusion ready for immediate administration if needed. In some instances a 5-cc syringe of 2% lidocaine was also prepared, to inject as a bolus if indicated for treatment of ventricular arrhythmias.[7] Lidocaine, isoproterenol, quinidine, atropine and propranolol were used with varied frequency. All patients were heparinized immediately and maintained on heparin for at least 24 hours. Long-term anticoagulant therapy was initiated and maintained with warfarin sodium. All patients were encouraged to use the bedside commode and were ambulated early.

External pacing was used very seldom, insertion of the transvenous bipolar catheter electrode was preferred and performed in the radiology department.[8] Routine orders included authority for the nurses to employ any emergency treatment indicated to include counter shock and/or pacemaking.

The Study

All cases showing a final diagnosis of acute myocardial infarction during 1968 were reviewed, this being the first full year of unit operation. The usually accepted diagnostic criteria for a proved myocardial infarction were used, namely: (1) A clinical history of typical pain, (2) classical sequential changes in the electrocardiogram, and (3) a changing elevation of at least one of the three serum enzymes: creatine phosphokinase, transaminase or lactic dehydrogenase. Using the criteria, it was found that a total of 33 proved cases of acute myocardial infarction were admitted to the hospital and treated in the unit during 1968. There were 52 other patients admitted during the year (Table). Some of them had been suspected of having acute myocardial infarction and some were admitted specifically for observation and treatment of previously recognized cardiac rhythm disturbances.

The average length of stay in the intensive coronary care unit for the acute myocardial infarction patients was five days and their hospital stay averaged 15.3 days. No patient was discharged from the hospital until he was ambulatory and free of significant cardiac symptoms.

Results

Mortality

In the group of 33 cases of acute myocardial infarction admitted to the unit during the year, there were six deaths (18%) during the entire hospital stay. These included five women (mean age of 76) and one man (age 84). The mean age of the group was 68. Congestive heart failure accounted for two of the deaths, a cerebral embolism caused one death, rupture of the ventricular wall and pulmonary embolism accounted for another death. The sixth death was due to cardiac asystole. The patient had an AV heart block and was scheduled for insertion of a transvenous pacing electrode, but insufficient urgency was ascribed to the matter and the patient suffered ventricular standstill which did not respond to external pacing. This was probably the only avoidable death in the series. There were no other deaths attributed to cardiac arrest per se.

For comparison's sake, an analysis was made of all cases of acute myocardial infarction admitted to the hospital in 1966, the latest full-calendar year preceding the opening of the coronary unit. It revealed a total of 24 patients with 11 deaths (46%).

TABLE
Type of Patients Admitted to the ICCU

	No. of Patients
Acute Coronary Insufficiency with Proved Infarction	33
Acute Coronary Insufficiency without Infarction	26
Major Cardiac Arrhythmias without Acute Coronary Insufficiency	15
Massive Gastrointestinal Hemorrhage	2
Severe Injuries	4
Diabetic Acidosis and other Medical Illness	5
TOTAL	85

Arrhythmia

Continuous monitoring in the intensive coronary care unit recorded arrhythmias in 31 of the 33 patients. Premature ventricular contractions occurred most commonly: in 30 (90%) of the patients. The most frequently employed anti-arrhythmic drug was lidocaine. External pacing was employed in two patients, both of whom died. Temporary pacing with a transvenous electrode was utilized in four patients, all of whom were ultimately discharged from the hospital in sinus rhythm. Ventricular fibrillation was treated by electroshock in three instances, once unsuccessfully and twice successfully. These procedures were also employed successfully on patients in the intensive coronary care unit during the year on other than those in the acute myocardial infarction group.

Comments

Early intensive coronary care units first established in 1962 have reported a significant reduction in mortality due to myocardial infarction. Compiled statistics of various units reveal a reduction in mortality ranging from 13% to 40%.[1-4] It has been found that the milder cases have a better prognosis for successful resuscitation in the event of cardiac arrest.

Of the total number of cases of suspected acute myocardial infarction admitted to our unit only 50% were subsequently proved to have had an infarction. This means that patients were admitted promptly and without selection. The 46% mortality observed in the 24 cases treated the year before opening of our intensive coronary care unit as compared to 18% mortality during the first year of our unit operation is, in spite of the small size of the series, probably proof enough of the value of the intensive coronary care unit in our small community hospital. Prompt medical treatment of arrhythmias in the intensive coronary care unit and subsequent reduction of the incidence of cardiac arrest may account for this gratifying result. Lown et al. have reported 130 consecutive cases without a single episode of ventricular fibrillation.[3] They attributed this to the change in emphasis from resuscitation to prompt medical treatment of arrhythmias. The ease of pacing the patient with AV block by the transvenous method has also played an important role. More recently pacing has been employed to treat repetitive ventricular arrhythmias.[10]

Conclusions

This study would indicate that the very small community hospital can establish an intensive coronary care unit with a degree of success proportional to the effort and diligence of its personnel and in so doing save lives that would otherwise be lost due to acute myocardial infarction. Moreover, it serves to improve the care to other patients with varying cardiac illnesses. Patients with "mild" myocardial infarction should be admitted to the intensive coronary care unit because the most rewarding results have been observed in this group.

Generic and Tradenames of Drugs

Lidocaine	Xylocaine
Isoproterenol	Isuprel
Propranolol	Inderal
Warfarin sodium	Panwarfin

Prolonged Oxygen Therapy and Mechanical Ventilation

Associated Pulmonary Abnormalities

GILES F. MacDONALD, M.D.*
DAVID E. DINES, M.D.†
ALAN D. SESSLER, M.D.‡
JACK L. TITUS, M.D.#
Rochester, Minnesota

Morphologic pulmonary lesions associated with prolonged oxygen therapy and mechanical ventilation have been described.[1-4] As far as can be determined, these changes have not resulted from the disease process that necessitated respiratory assistance; in fact, many patients have not had primary cardiopulmonary disease before the use of assisted ventilation.

In 1966 one of us (J.L.T.) noted that the lungs of patients having assisted ventilation immediately before death showed histologic changes which did not fit into any of the usual categories of lung pathology. Since administration of oxygen or assisted ventilation or both were considered to be etiologic factors at that time, and in view of the recent reports,[1-4] the present study was done.

Materials and Methods

The gross morphologic and histologic features of the lungs of 35 patients who died while on assisted ventilation or on high concentrations of oxygen were studied at autopsy. For comparison, the morphologic findings from 40 examples of organizing pneumonia, 30 examples of pulmonary edema of various types and causes, and 30 examples of pneumonias of various etiologies were reviewed. Histologic sections from each lobe of both lungs of each patient in all the groups were reviewed independently and without any knowledge of clinical data.

The clinical records of the 35 patients who received assisted ventilation or high concentrations of oxygen were then reviewed to ascertain the major disease states, reasons for and duration of administration of oxygen and assisted ventilation, arterial oxygen tensions achieved, results of tests of pulmonary function, and therapeutic measures utilized.

*Present address: General Hospital, Edmonton, Alberta, Canada.

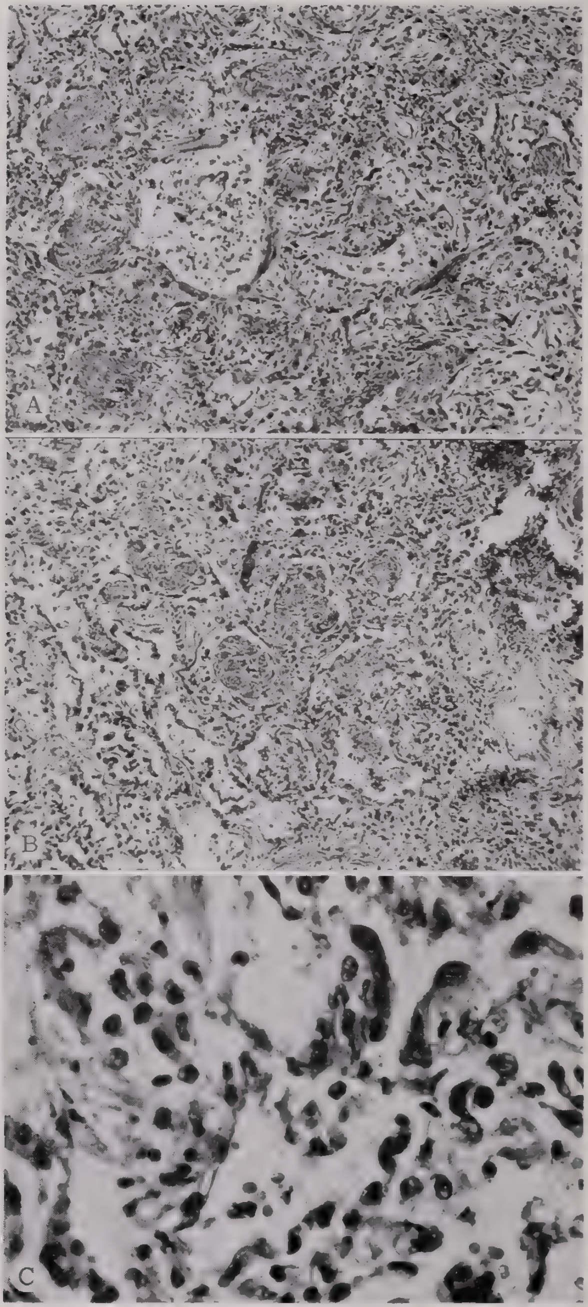

Fig. 1—Morphologic pulmonary lesions. (A) Intra-alveolar deposits of fibrin, hyaline membranes, prominence of alveolar lining cells, intra-alveolar septal thickening with fibroblastic proliferation, and infiltration of chronic inflammatory cells are present. (Hematoxylin and eosin; reduced from x105.) (B) Alveolar septal thickening is more apparent in this area from same case as Figure 1(A). (Hematoxylin and eosin; reduced from x105.) (C) Higher power view of lesion in another case demonstrates prominence of alveolar lining cells (upper right) and nature of inflammatory cells. (Hematoxylin and eosin; reduced from x520.)

Morphologic Features

Weight

Grossly, the lungs of 20 patients with the histopathologic findings tended to be heavy, congested, and firm. The other 15 of the 35 cases did not have these morphologic features. The lung weights in these 20 adults varied greatly, from 655 to 2,860 gm with a mean of 1,580 gm. The mean lung weight of the 100 examples of pneumonias and pulmonary edema was 1,235 gm.

Histologic Changes

The characteristic histologic picture in seven of the 35 cases consisted of intra-alveolar deposits of fibrin, hyaline membranes, thickened alveolar septa with fibroblastic proliferation, prominence of alveolar lining cells, and infiltrates of chronic inflammatory cells (Figure 1A B, C). These 20 cases could be distinguished from pulmonary edema, organizing pneumonia, and the usual varieties of pneumonias by the histologic findings alone.

Clinical Features

The following clinical aspects pertain to the 20 patients in whom the aforementioned morphologic features were present. The 12 males and eight females ranged in age from 15 to 71 years with a mean age of 46 years.

The primary diagnosis is disclosed in Table 1.

Clinically, the respiratory diagnoses were bronchopneumonia in 10 patients, respiratory failure in seven, and aspiration pneumonitis in three.

TABLE I.
Primary Diagnosis (20 Patients)

Traumatic cerebral contusion	5
Metastatic malignancy	5
Primary pulmonary disease (emphysema and chronic asthmatic bronchitis)	2
Respiratory failure (Guillain-Barré syndrome)	2
Systemic lupus erythematosus, tetanus, hepatic coma, coronary heart diseases, postoperative conditions	6

Congestive heart failure was diagnosed in 12 of 20 patients as a terminal event. Seven of the 20 had received vasopressor drugs to sustain blood pressure during their terminal illness. Twelve had received corticosteroid preparations; these were given to five patients for cerebral edema, to three for aspiration pneumonia, to two with hepatic coma, to one patient with asthmatic bronchitis, and to one who had tetanus with evidence of adrenal insufficiency.

Ventilation was carried out through a tracheostomy in 18 of the 20 patients and through an endotracheal tube in the other two.

Laboratory Studies

X-ray Findings

Roentgenograms of the thorax showed evidence of abnormalities in 18 of the 20 patients; 16 had bilateral pulmonary infiltrates (Figure 2) suggestive of pneumonitis with varying degrees of atelectasis and pulmonary vascular congestion, and the other two showed evidence of pleural effusions.

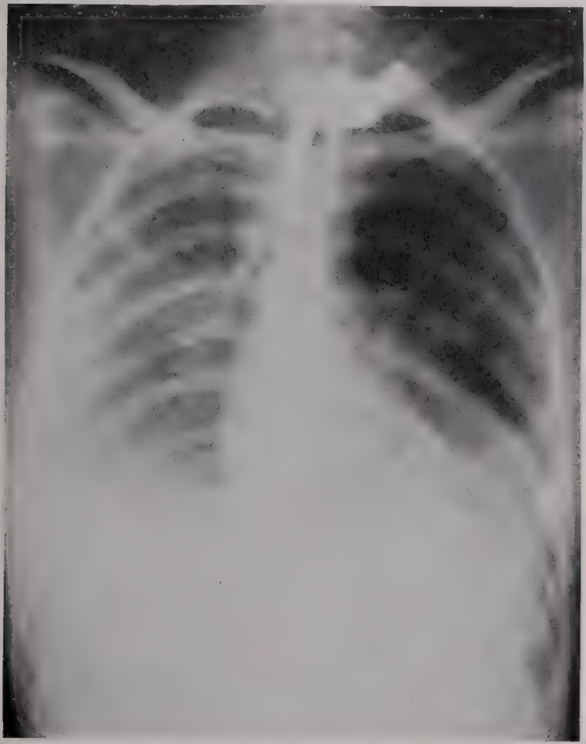

Fig. 2—Example of x-ray pattern of bilateral pulmonary infiltration found in many patients.

Bacteriology

Pathogenic bacterial organisms were cultured from the tracheas of eight of the 20 patients. The organisms obtained were *Pseudomonas* from three, *Diplococcus pneumoniae* from two, *Mima polymorpha* from one, *Bacterium anitratum* from one, and *Alcaligenes faecalis* from one.

Arterial Oxygen

Arterial oxygen levels were measured in 18 patients during the acute phase of the terminal illness; 14 were ventilated with a machine set to deliver 40% oxygen; but the inspired concentration of oxygen probably approximated 60 to 80% since all of these ventilators had humidifiers and nebulizers fed by 100% oxygen. In these 14 patients the observed arterial oxygen tension (Pa_{O_2}) was less than might have been anticipated even if the gas received had contained only 40% oxygen (Table 2). The arterial oxygen tensions in the other four patients who were ventilated with 100% oxygen were also far below the expected normal value for that inspired concentration (Table 3).

TABLE 2.

Arterial Oxygen Tensions in Patients to Whom "40% Oxygen" Was Being Administered Prior to Death

Case	Arterial oxygen tension (Pa_{O_2}),* mm Hg	Days of therapy
1	175	13
2	59	22
3	73	15
4	57	120
5	46	17
6	61	37
7	64	3
8	45	13
9	81	19
10	86	5
11	55	9
12	103	11
13	103	9
14	71	11

*Pa_{O_2} should be approximately 250 mm Hg when fraction of inspired oxygen (FI_{O_2}) = 0.4.

TABLE 3.

Arterial Oxygen Tensions in Patients to Whom 100% Oxygen Was Being Administered Prior to Death

Case	Arterial oxygen tension (Pa_{O_2}),* mm Hg	Days of therapy
15	55	3
16	161	4
17	192	32
18	255	14

*Pa_{O_2} should be approximately 600 mm Hg when FI_{O_2} = 1.0.

Comment

In the 20 patients who died after mechanical ventilation and who had received oxygen at concentrations of 40% or more, the primary diagnosis did not appear to be etiologically significant in the production of the morphologic pulmonary abnormalities. Only one patient had had previous cardiopulmonary disease—a 71-year-old man with emphysema. The respiratory diagnoses of aspiration pneumonia in three patients and bronchopneumonia in 10 probably were not of etiologic significance since 30 patients with various types of pneumonia did not show similar morphologic features. Likewise, pulmonary edema, noted clinically in 12 of the 20 patients as a terminal event, did not seem to be of etiologic significance in the genesis of the pulmonary lesion, because 40 other patients having pulmonary edema did not have the morphologic changes present in the study group.

Drug therapy, including steroids in 12 patients, could not be related to the occurrence of the pulmonary lesion. The difference in histologic features between the 20 patients and the group with pneumonia made infection an unlikely factor in the pathogenesis of the condition. The gram-negative organisms found in six patients most likely reflected contamination introduced through their tracheostomies or from inhalation therapy equipment.

In 19 of the 20 patients, the period of mechanical ventilation ranged from three to 120 days. Although one patient was not ventilated, the same morphologic changes developed after four days of breathing from a mask which delivered 100% oxygen. The only common etiologic factor that could be identified in all patients was the administration of oxygen at high tensions or mechanical ventilation for three or more days.

Morphologically, the commonest gross appearance was one of heavy, firm lungs as described previously by Nash and associates.[1] The mean lung weights of the 20 patients were greater than those of the patients who had other pulmonary abnormalities and who also had greater than normal lung weights. Occasionally, however, the lung weights may be nearly normal in patients who have typical histologic features, as exemplified by one case in the present study in which the total weight of the lungs was 655 gm. The unusual histologic appearance of intra-alveolar deposits of fibrin, hyaline membranes, thickened interalveolar septa, enlarged alveolar lining cells, and chronic inflammatory cellular infiltrate was found to be a distinctive pattern that differentiated patients who had oxygen therapy and assisted ventilation from the control group who had pulmonary edema, organizing pneumonia, and bronchopneumonia owing to various causes.

Conclusion

Histologically, intra-alveolar deposits of fibrin, hyaline membranes, thickened alveolar septa with fibroblastic proliferation, prominence of alveolar lining cells, and infiltrates of chronic inflammatory cells were apparent and seemed specific for the condition.

Histologic changes were present in 20 of the 35 cases. These 20 could be distinguished from pulmonary edema, organizing pneumonia, and the usual varieties of pneumonia by the histologic findings alone. Nineteen of the 20 patients had had assisted ventilation for three to 120 days. The 20th patient had breathed for four days from a mask which delivered 100% oxygen but had not received assisted ventilation. All 20 patients had low partial pressure of oxygen in the arterial blood.

We have concluded that gross and histologic abnormalities occur in the lungs of patients who have been exposed to prolonged mechanical ventilation and to high oxygen concentration. The etiology of these changes may be related to high oxygen tension or inactivation of surfactant,* but we have no evidence from this small retrospective study what the exact mechanism is.

Make good or make room.—Forbes Epigrams

Let's be specific about Campbell's Soups...
and *reducing diets*

Calorie content of Campbell's Soups

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Campbell's
SOUP

NOW IS THE TIME... TO GIVE HER TIME WITH OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The new mother needs time...
to adjust to motherhood,
to give her new baby all the love
and attention he requires.
She needs time for her husband...
and for herself as well...
so that she can come to terms
with the increased cares
and responsibilities now facing her.
She needs time to decide
when she will have additional children
and how many she will have.

OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

GIVES HER TIME

Your prescription for Ovulen-21 gives the new mother time to meet her family's present needs...to plan for her family's future.

She can take Ovulen-21 confidently and comfortably month after month. Its dependability is enhanced by its simplicity of use. A woman needs little or no time to learn the simple Ovulen-21 regimen: three weeks on—one week off. And the automatic record-keeping of the petite, virtually "patient-proof" Ovulen-21 Compack® helps to maintain her schedule...helps put time on her side.

Immediately post partum is the time

It is the time when motivation is highest—when a new mother needs expert advice for the future, so she can space her children and limit her family.

It is also the most opportune time, since she is conveniently present in the hospital, for her to be given both instructions and a prescription.

Non-nursing mothers may begin Ovulen-21 immediately after delivery, on the day of departure from the hospital or at the first postpartum visit, as desired. It is recommended that nursing mothers begin Ovulen-21 four weeks after delivery.

A small fraction of the hormonal agents in oral contraceptive pills has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching. The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

SEARLE

What's Polycillin® (ampicillin trihydrate) got to do with the price of bananas?

Just this: According to the U.S. Bureau of Labor Statistics, bananas are one of the few things that actually cost less today than five years ago. The same is true of Polycillin. In fact, the price of Polycillin has been reduced about 30% since its introduction in 1963...making it, according to national surveys of patient costs, as economical as leading brands of tetracycline and erythromycin.

And Polycillin is available in a variety of dosage forms for your patients—more than any other ampicillin. It comes in 250 mg. and 500 mg. capsules; in convenient, chewable tablets of 125 mg; oral suspension, 125 mg. and 250 mg. per 5 ml.; and in pediatric drops, 100 mg. per ml. Also available parenterally as Polycillin-N (sodium ampicillin).

Pernicious Anemia

PERNICIOUS ANEMIA is one of the diseases that make the practice of medicine rewarding. The patient, often seriously ill, is restored to complete health by simple measures. The response is predictable. The physician has a feeling of self satisfaction not only at making the diagnosis but in so readily curing an illness formerly fatal.

The story of pernicious anemia is one of the triumphs of modern medicine, with the discovery of the therapeutic effect of liver by Minot and Murphy, the experiments of Castle on the anti-pernicious anemia principle, and the isolation and synthesis of vitamin B12. Glass' two hundred and seventy-three page article on the intrinsic factor with its 1311 references clearly attests to the continued interest in this field.[1]

The February issue of Minnesota Medicine* contains an article on the occurrence of pernicious anemia in two American Indians. The authors point out the rarity of this anemia in individuals of presumed Oriental origin, including Eskimos and North American Indians. In both cases the disease had primarily neurological manifestations with only moderate anemia. Whether or not such a pattern is generally true in individuals of this descent is not evident from the literature. Administration of folic acid will produce hematological remission but apparently provokes the onset of subacute combined degeneration. Duration of illness prior to therapy is important; otherwise we do not know why some individuals are more prone to the neurological manifestations. Difference in racial susceptibility might well offer a clue.

Current interest centers around the question of whether pernicious anemia is an auto-immune disease. A high incidence of antibodies against thyroid, parietal cells of the stomach, and intrinsic factor has been found in patients with pernicious anemia. It has been proposed that the fundamental defect in this disease is the production of antibodies which bind intrinsic factor, subsequently preventing the absorption of vitamin B12. The frequent occurrence of the antibodies has been clearly demonstrated. Whether or not they are of significance is uncertain, for they are not always found. Pernicious anemia occurs in immunologically deficient people, etc.[2,3]

The precise biochemical action of vitamin B12 is under investigation. Megaloblastic anemia is believed to represent a partial failure of DNA synthesis relative to that of cytoplasmic RNA; hence the maturation arrest of the nucleus with a "young" nucleus and "old" cytoplasm. Coenzyme B12 appears to be involved in multiple metabolic systems; it is required in the succinic† acid cycle, the synthesis of proteins, the function of sulfhydryl-activated enzyme systems, the synthesis of deoxyriboside, etc.[4] It is also essential for "normal growth and nutrition, normal hematopoesis, normal

Three Problems—One Solution

THE NEEDS OF THE community, or the individual, frequently come at inopportune times and require inefficient, inconvenient, and expensive solutions. Thus, when we observe several community needs and the opportunity to serve all with one stroke, we gain convenience, efficiency, and economy. This plan, which could simultaneously resolve a current problem (what to do with Gillette Hospital) and advance the solution of two other problems (increasing the number of physicians in Minnesota and improving the care of children crippled by chronic disease), deserves debate.

Problem one—Gillette State Hospital for Crippled Children was studied by a Subcommittee of the Minnesota Senate Public Welfare Committee. The last paragraph of the Committee's report stated:

> "In the final analysis, the question of continuing Gillette revolves around considerations of the total program of care and treatment supported by the State for handicapped children, the extent to which existing programs at Gillette can be continued at a reasonable cost, and the extent to which new facilities can be provided which are flexible enough to be changed as needed in keeping with changing trends and needs for patient care."

Problem two—increasing the number of physicians in Minnesota. Recommendations have been made to increase the number of medical students at the University Medical School from 150 to 200 and to develop graduate basic science programs at the University of Minnesota, Duluth, with eventual use of this base to form a four-year medical school. Increased funds for construction of additional beds will be required to provide care for the patients needed to train these additional doctors.

Problem three—children crippled by chronic disease. At one time the term "crippled child" meant the child who was handicapped by a skeletal or neuromotor disease. The problems encompassed by this old concept have changed radically in the past twenty years. Three of these diseases, poliomyelitis, osteomyelitis and tuberculosis, which once caused one half of Gillette Hospital admissions, have almost vanished. The remaining crippling problems are proving more complex; to accomplish rehabilitation the orthopedic surgeon requires other medical specialists to aid in the care of afflicted patients. This evolution of understanding that social, psychiatric, sensory, and learning problems can be additional handicaps to the orthopedically crippled child has been accompanied by a recognition that children handicapped by other chronic diseases can also be crippled in their ability to achieve their optimum potential in their pursuit of self-expression and development.

Today the Crippled Children Services of the United States Government recognizes that a crippled child is one who "has an organic dis-

Dulcolax®...so predictable you can almost set patients by i

Dulcolax works so effectively that the time of bowel evacuation can often be predicted.

Dulcolax tablets taken at night will usually result in a convenient bowel movement the following morning. Dulcolax suppositories generally work within 15 minutes to an hour.

Dulcolax may be given to the aged, pregnant or nursing women, and children. It may be particularly helpful in conditions in which straining should be avoided. The drug, however, is contraindicated in the acute surgical abdomen.

Dulcolax® bisacodyl

UNDER LICENSE FROM BOEHRINGER INGELHEIM G.M.B.H. GEIGY PHARMACEUTICALS, DIVISION OF GEIGY CHEMICAL CORPORATION, ARDSLEY, NEW YORK 10502 ease, defect or condition which may hinder the achievement of normal growth and development."

The broadened scope of this definition extends support for the care of children beyond the traditional limits of orthopedic conditions. In Minnesota such other diseases include surgically treatable defects of the skin, both congenital and acquired, including burns; heart lesions amenable to surgery; dental handicapping conditions; hearing defects; cystic fibrosis; mentally retarded patients with treatable physical handicaps, plus other handicapping conditions amenable to treatment, whether gastrointestinal, genital-urinary, pulmonary neurologic or inherited.

Some children with some of these crippling diseases fail to obtain their maximum potential because they have no access to physical facilities for specialized long-term care such as exist for orthopedic problems in Gillette State Hospital and the Shriner's Hospital for Crippled Children. Optimum care cannot be provided for many of these children until rehabilitation facilities are created which can provide such long-term care for patients with any of these problems.

Solution—Build a new Gillette State Hospital for handicapped children as a 350-to-450-bed children's hospital into the hospital complex at the University of Minnesota Medical School or as a smaller children's hospital in Duluth, to be the first building of the University of Minnesota—Duluth Medical School.

Such a decision would permit maintenance of a historic hospital and would establish a needed and now non-existent facility that could provide total comprehensive and consultative care for children with all varieties of acute and chronically-handicapping disorders. In either location such a new Gillette State Hospital for Handicapped Children would simultaneously resolve some of the problems in the cost of developing more doctors and some of the problems of chronically handicapping childhood diseases. Any other solution would require two or three comparably expensive decisions to approximate the effects of this one. If Gillette State Hospital for Crippled Children is rebuilt as a narrowly directed Children's Orthopedic Hospital, additional facilities will still be needed to provide care for the other chronic childhood disease problems; otherwise we will continue to provide less than adequate care for some of these children and eventually incur increased expenses through support programs for disabled adults.

Rebuilding Gillette Hospital as a hospital for chronic children's diseases as a State Children's Hospital at the University of Minnesota or as the first building of the University of Minnesota—Duluth Medical School would conveniently and economically resolve the problem of what to do about Gillette Hospital, speed the training of additional physicians in Minnesota and provide a needed facility for care of children with many non-orthopedic crippling diseases.

The Human Use of Human Machines

THE TROUBLE with doctors as scientists is that they tend to act like humans. Take, for example, the act of listening to a heart. Every listener responds differently to the same sounds. Indeed, the same observer on different occasions may interpret the same sound differently, depending on his inner ear, his mood, and his prejudices. Which should come as no surprise since cochlea, like minds, aren't always cocked at the same angle.

Auscultation, then, is a subjective act, subject to human frailties. To use computer talk, the mind's ear supplies only "soft data." But, no matter; as every modern schoolboy knows, machines can harden the softest figures.

They can do something else, too. As Doctor Wanamaker points out in a previous issue of *Minnesota Medicine,** a machine (in this case a phonocardiogram) can teach. By providing a graphic record, the phonocardio-

gram lets the physician "see" what he heard, tells him something of a lesion's severity, and provides a record for future scrutiny. And, to quote Doctor Wanamaker, it ". . . can teach the important lesson of humility and serve as a valuable supplemental method of study."

But before you leap to the conclusion that the machine will take the guess-work out of listening, consider another piece of work. With a machine (this time a phonocardioscan), investigators at the Permanente Medical Group in California auscultated the hearts of 456 adults and then compared the results with those obtained by internists.[1] The machine didn't fare too well. Of the murmurs it detected, a third turned out to be insignificant. And when murmurs were present, it missed a fourth of them.

The conclusion? "At its present stage of development, the machine was considered insufficiently sensitive and specific for incorporation into a multiphasic health appraisal examination of adults." Take heart. Maybe machines are human after all.

Chronic Respiratory Disease in Children

Dr. Edwin Kendig* states in his review: "Chronic respiratory disease in children has been considered unglamorous." However, the content of the articles on this subject in the September issue of MINNESOTA MEDICINE indicates that much progress is being made in this field, both diagnostically and therapeutically. In pulmonary function studies the exceedingly complex metabolic function of the lung is being appreciated, as pointed out by Dr. V. Chernick,* and sophisticated radioisotope studies have been described by Dr. Jose R. Medina* in localizing pulmonary functional lesions. Newer concepts regarding the pathogenesis of cystic fibrosis are presented by Drs. Alexander Spock* and Gordon E. Gibbs,* and Dr. Malcolm N. Blumenthal* has reviewed very clearly the current knowledge and controversies regarding the etiology of bronchial asthma. Dr. Norman Hepper* presents current data on the effects of cigarette smoking in the production of chronic respiratory disease and Dr. LeRoy W. Matthews* has explained the role of inhalation therapy in its management. Dr. Richard Hong's* excellent conceptualization of the physiology of immunity is especially worthy of review.

For the "front line" physician, seeing children in health and disease, a most important contribution is the article by Dr. William Waring* on the clinical evaluation of the child with chronic lung disease. Clinical awareness of chronic respiratory disease which often begins insidiously in childhood may be greatly enhanced by the routine use of the rather simple quantitative techniques described by Dr. Waring. Accurate counting of the respiratory rate (which may best be done by enlisting the help of parents during the child's sleep), measurements of thoracic depth and width with obstetrical calipers and a simple clinical evaluation for clubbing of the fingers provide easily obtainable data. These measurements provide a base line for suspicion of developing disease and a way to follow its progress. The advantage of this kind of measurement is that it is not effort-dependent on the part of the child. Anyone who has worked extensively with pulmonary function testing in children realizes the need for simple diagnostic tools for case finding. Cough, as a pediatric symptom, is so ubiquitous that it may be easily disregarded, but chronic cough (daily for three months or more) must be taken seriously, as Drs. Waring and Harris* point out.

Bronchial asthma, as an example of the most common of chronic respiratory diseases in children, is a major interest of the pediatric aller-

Dear Doctor:

Two common geriatric and pre-geriatric vasospastic states, cerebral ischemia and myocardial ischemia, have been shown to be helped by papaverine when administered in a form which provides gradual release of the drug. Just such a form for continued release is found in VASOSPAN containing 150 mg. of papaverine hydrochloride in an efficient sustained-release capsule.

"Emphasis on Flow" is the aim of treatment and the accomplishment of VASOSPAN in these conditions. And it's done economically, too—a matter of no little importance to the geriatric or pre-geriatric patient. With VASOSPAN there is a comparatively rapid early release for prompt relief, and a prolonged release for continued relief.

The following benefits can be expected from sustained-release papaverine with regard to the forgetfulness, confusion and irritability of cerebral ischemia or the recurrent anginal discomfort of myocardial ischemia:

Pharmacologically, papaverine acts on cardiac and smooth muscle[1,2] including the arterial musculature of cerebral[2] and coronary[3] vessels.

Clinically, papaverine is employed for its vasorelaxant (dilator) action rather than an analgesic in coronary vasospastic conditions[4] and for symptomatic benefit in cerebral ischemia not caused by advanced arteriosclerosis.[5,6]

Sincerely,

A. W. Wilber

"Emphasis on Flow"
VASOSPAN™

(papaverine HCl 150 mg.)
Sustained Release Capsules

Each capsule contains papaverine hydrochloride, 150 mg., in timed disintegration pellets for sustained release. Class M exempt drug. *Indications:* Relief of cerebral and peripheral ischemia associated with arterial spasm, and myocardial ischemia complicated by arrhythmias. *Side Effects:* Rarely nausea, abdominal distress, anorexia, constipation, malaise, drowsiness, vertigo, sweating, headache. *Contraindications:* Use with caution in patients with glaucoma. *Dosage:* 1 capsule every 12 hours. May be increased to 1 capsule every 8 hours.

gist. Besides its prevalence an important facet of bronchial asthma in childhood is its reversibility. While the long-term natural history of bronchial asthma is poorly understood. Rackemann's study* indicated that 70 per cent of children with asthma are virtually symptom-free by age 20.

However, any physician who cares for children with asthma realizes what a disabling disease it can be, both physically and psychologically. As a major cause of school absence among chronic diseases, childhood bronchial asthma also is a community problem. Overprotection and sheltering of the child with asthma, often fostered by physicians' rigid and authoritarian instructions to well-meaning parents, have made the child with asthma fearful, inhibited and of low self-concept. At the other end of the spectrum, casual treatment of bronchial asthma in the child, while waiting for "tincture of time" to solve the problem, can lead to much unnecessary suffering, self-depreciation and disability.

What is needed is a vigorous, reasonable multi-disciplined approach to the problem of the child with bronchial asthma which leads to the acceptance of his limitations by the child, his family, and the community. These limitations should be determined, not by fear and admonition, but by experience with, and observations of, the individual child. Parents, physicians, vocational counselors, school nurses, educators, physical education directors and all others involved in the health supervision of children, must be made aware of these concepts.

Programs to improve the quality of life for children with asthma, such as the physical conditioning and parent education courses sponsored by the Respiratory Disease Associations of both Hennepin and Ramsey Counties, the Asthma Camp, similarly supported, and the adaptive physical education programs in some of the public school systems are important approaches in action now. Expansion of services such as these to other areas of the state deserve our active support.

You May Be Right

The legitimate purpose of a journal is educational and the legitimate concern of our state journal's editor is the quality of education in Minnesota. I was, therefore, pleased to see Dr. Rice asking hard questions about a particular educational program in Minnesota sponsored by the Regional Medical Programs. The Regional Medical Programs were conceived by our Federal Government to meet pressing needs to educate doctors far removed from medical centers in the latest management practices for certain diseases—particularly cancer, heart disease and stroke. Thousands of patient lives would be saved, it was felt, if only the out-lying physicians could be taught how to manage their patients "properly." An elaborate well-funded program was established in many regions across America in response to this need and our State established the Northlands Regional Medical Program. Enthusiasm ran high and many factions in the State of Minnesota became involved. An organization was set up and staff was hired. All this took place some years ago.

Now concerned physicians must ask, "What has been done by the Northlands Medical Region Program? What is being done currently and what plans are being laid for the future? Are physicians in the peripheral areas of Minnesota being served regarding their educational needs or has the government merely created still another bureaucratic self-serving institution which does not meet the needs of doctors and their patients? Have valuable tax dollars been invested wisely in medical and paramedical educational programs in our State or are existing facilities being duplicated?"

Dr. Carl Rice has focused attention on one of the activities of the Northlands Regional Medical Program—namely, the canned consultation whereby physicians may call a number and receive a transcribed message regarding a medical problem. He pointed out that consultants in the State abound and a phone call to any would surely bring about a response and the referring physician would at least have a chance to interact with the respondent. Traditionally, medicine has been practiced by fostering warm interchanges among colleagues. The tax dollars spent on developing the canned program might better have been invested in medical and paramedical personnel, on defraying expenses of trained medical teachers invited to peripheral hospitals to talk and interact with their colleagues. The questions raised in Dr. Rice's insightful soliloquy are most serious and should foment doubts in the minds of all concerned physicians about the value of the Northlands Regional Medical Program. Perhaps it is time that our State Medical Journal lend its influential voice to an inquiry as to what our Regional Medical Program is doing. Perhaps it is time for concerned readers of Minnesota Medicine to have answers regarding the expenditure of funds ostensibly for their benefit.

You May Be Right

(Continued)

You May Be Right, but . . . had I edited the October issue of MINNESOTA MEDICINE, I would have reversed, on page 1639, the position of the Editor's Soliloquy, and the immediately following quotation from Old Doc Hess.

I like an apertif to sharpen my perceptions, and alert my comparative conclusions.

R. P. Buckley, M.D.
Duluth, Minnesota

You May Be Right but . . . Your comments with regard to "Canned Consultation"* were of interest and I might add that one and a quarter million dollars is sufficient to provide a comfortable income for 40 fulltime physicians or, in lieu of that, the care of the doctor bills for 4,000 families through the Medallion plan of the Minnesota Blue Shield. L.G.

---

*Minnesota Medicine 52:1639, 1969.

I read with interest the article entitled "Infarct of the Prostate Causing Pyohydronephrosis" by Stanley J. Antolak, Jr., M.D., in the April 1969* issue of MINNESOTA MEDICINE. I think Dr. Antolak is to be congratulated on his carefully planned and essentially conservative and successful therapy of this difficult problem.

However, I do not agree with the interpretation placed on the finding of the infarct of the prostate. I think a much more likely cause for the anuria and distal ureteral obstruction is impaction of cellular or calculous debris from the already infected kidney. The temporary obstruction at the left ureteral orifice relented sometime after the performance of the nephrostomy and again urine passed freely into the bladder.

I feel that there is no reason to suspect that the infarct is other than an incidental finding noted only because the patient subsequently underwent transurethral resection of the prostate gland. I can think of no physiopathologic process that would allow infarction in the left posterior apical segment of the prostate to cause distal ureteral obstruction. The 43-year history of urinary calculi is reason enough for the phenomenon noted.

J. M. Streitz, M.D.
Duluth, Minnesota

The Editor's Soliloquy

LEGALLY CORRECT

Years ago when I began the practice of surgery, it was customary to insist that the pathologist find an abnormal cell in a normal appendix for fear of being legally incriminated for the removal of a normal, though useless, organ. Surely there were not many instances in which the surgeon deliberately removed a normal appendix, though in the interest of choosing a less hazardous course in preference to the risk of a greater mortality, a surgeon did occasionally find that the appendix was normal.

Within a few years this trend was reversed on the basis that there was no legal liability when a justifiable error in diagnosis had to be admitted to the anxious parents. Forthright integrity prevailed and no official document was necessary to maintain the legality of the appendectomy.

In recent years it seems that a proportionately large percentage of the budgets of medical societies is being expended for non-scientific ventures. Might it not be wiser to allocate a greater proportion of the budget to our major educational pursuits. With intellectual integrity it would normally follow that there would be fewer libelous things to fear. In that high-grade, honorable medicine can be practiced only by staying abreast of the scientific advances through conscientious study, reading of medical literature, and attendance at scientific meetings, is it possible to stay within the intellectual field of medicine. A few extra dollars for that purpose should not be catastrophic.

Carl O. Rice, M.D.

OLD DOC HESS SAYS: Fear not a legal liability—for if, in the practice of your profession, you are intellectually honest, you will in all probability be legally correct.—C.O.R.

Guest Consultant

At parties he's in much demand:
The hostess seats him close at hand
And all the guests are pleased as Punch
He came to dinner or to lunch.

And is he, then, a beau, a wit,
By whom the ladies like to sit?
Oh, no—each hopes the guest M.D.
Will diagnose her ailments free.*

Thinking

I wrote somewhere once that the third-rate mind was only happy when it was thinking with the majority, the second-rate mind was only happy when it was thinking with the minority, and the first-rate mind was only happy when it was thinking.
—A. A. Milne

President's Letter

(Continued from Page 1723)

mittees of physicians to prevent such overutilization. Here again the American Society of Internal Medicine is active in implementing and properly directing the quality and utilization control committees.

Only major problems have been alluded to here. It is apparent, however, that many dedicated physicians are giving a great deal of time to achieving the aims of the American Society of Internal Medicine. Unless more of us are willing to forego our usually passive role and help direct the changes which keep occurring in medicine, we will find ourselves in danger of having our freedom limited because we have not stood up to our responsibilities.

Herbert W. Johnson, M.D.
President
Association of Minnesota Internists

Man Facing Man

All medicine, the magical and mysterious relationship between physician and patient, which contributes so much to the healing process, is founded on knowing how to produce a good clinical case history. I prefer a good clinical case history, based on a naturalistic and psychological criterion, to the best laboratory reports. In turn, the dialogue with the patient, which makes a good clinical case history possible, is in itself incontestably a healing function.

A man is facing another man. They are alone. Even if there were people around them, they would still be alone in the seventh solitude of their mysterious relationship. One of them is ill and in pain. The other knows how to alleviate him.

They may be standing by the pyramid at Sakkara five thousand years ago under the blazing Egyptian sun; or in the shade of a palm tree on the island of Cos some twenty-four centuries ago; or at the papal court of Avignon during the Black Death; or in the palace of a sixteenth-century Italian doge; or in the London of James I in the sanctum of a physician who impatiently glances at his timepiece wondering if he will be late for the new Shakespeare play at the Globe Theater; or in Maria Theresa's imperial Vienna, famous for music and medicine; or in the Necker Hospital in Paris in the days when the memory of Napoleon still sent cold shivers down the spines of the monarchs of Europe; or in Boston where for the first time tremendous progress in neurosurgery is being made; or in the New York of modern skyscrapers and electronic marvels.

One of the two men is a patient. The other is a physician, and he may bear the name of Imhotep, Hippocrates, Guy de Chauliac, Fracastoro, William Harvey, Auenbrugger, Laennec, Cushing, or that of a New York physician of our own day.

A simple inspection of that scene between the two men, of the act of diagnosis, which is at the same time prognostic and curative, teaches us something very important. Through the centuries, for some six thousand years now, the patient has not changed. His *history,* his biographical adventure has changed, but his nature has always remained the same. But the physician has changed. His knowledge, his technique, his social standing have all changed, though not his healing mission nor his humanitarian ethics. No, the patient has not changed during all those centuries, but the physician has and with him the world of medicine.*

Painful night leg cramps...

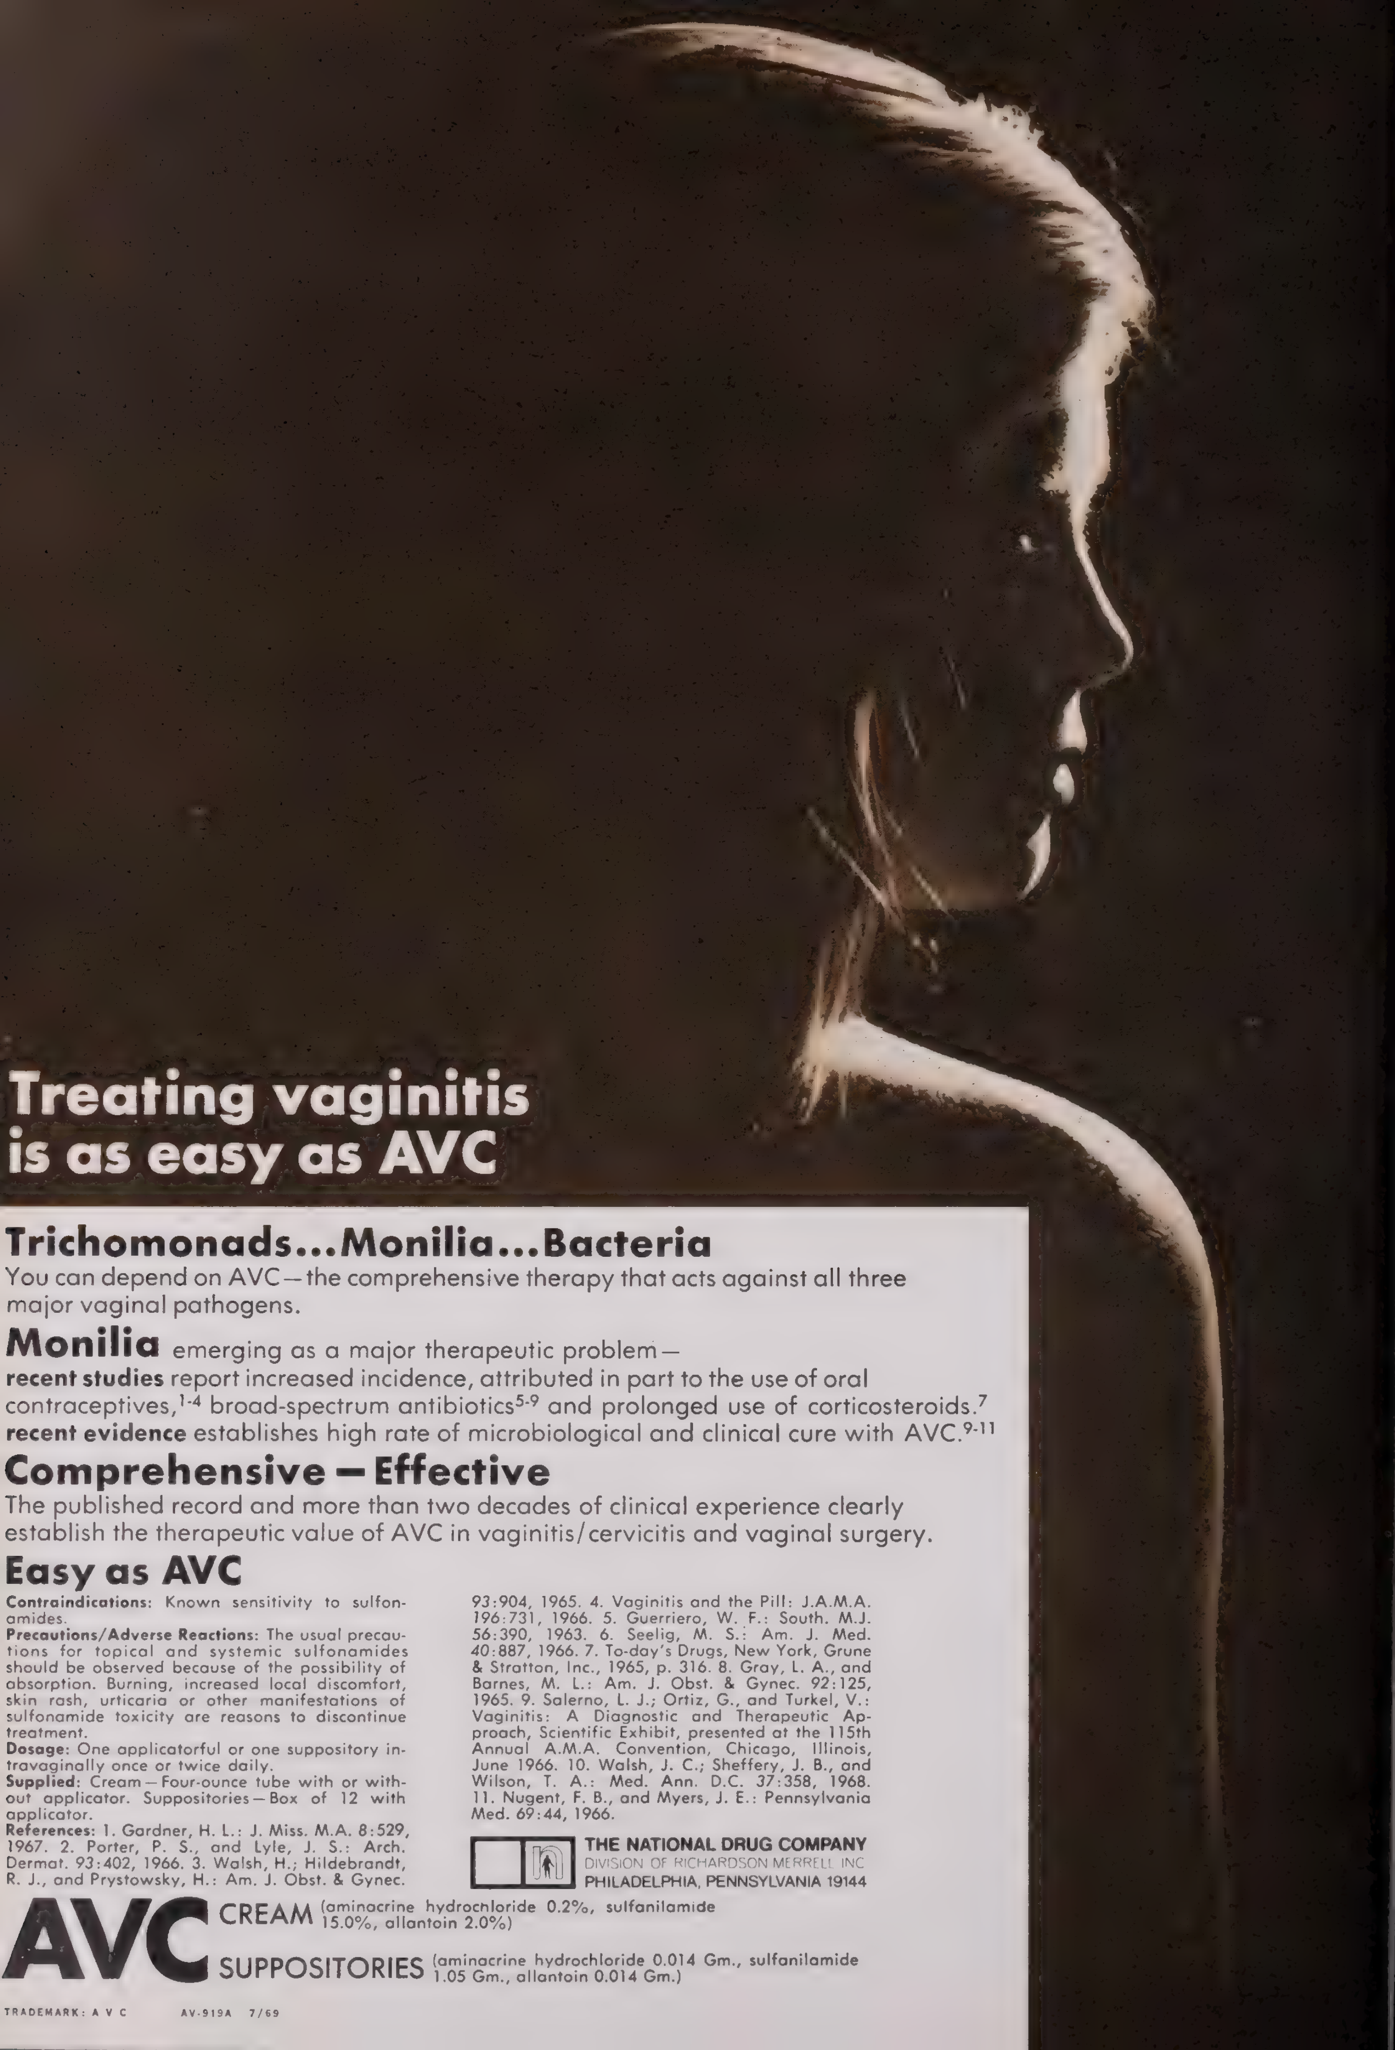
unwelcome bedfellow for any patient–including those with arthritis, diabetes or PVD

One thing patients can sleep without, particularly patients with chronic disease conditions such as arthritis, diabetes or PVD, is painful night leg cramps. Although seldom the presenting complaint, night leg cramps can tie your patients up in painful knots. Now, just one tablet of QUINAMM at bedtime can usually bring an end to shattered sleep and needless suffering. Your patients will sleep restfully—gratefully—with QUINAMM, specific therapy to prevent painful night leg cramps.

Prescribing Information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON-MERRELL INC.
PHILADELPHIA, PENNSYLVANIA 19144

Quinamm™ Specific therapy for night leg cramps
(quinine sulfate 260 mg., aminophylline 195 mg.)



Treating vaginitis is as easy as AVC

Trichomonads...Monilia...Bacteria

You can depend on AVC—the comprehensive therapy that acts against all three major vaginal pathogens.

Monilia emerging as a major therapeutic problem—
recent studies report increased incidence, attributed in part to the use of oral contraceptives,[1-4] broad-spectrum antibiotics[5-9] and prolonged use of corticosteroids.[7]
recent evidence establishes high rate of microbiological and clinical cure with AVC.[9-11]

Comprehensive—Effective

The published record and more than two decades of clinical experience clearly establish the therapeutic value of AVC in vaginitis/cervicitis and vaginal surgery.

Easy as AVC

Contraindications: Known sensitivity to sulfonamides.
Precautions/Adverse Reactions: The usual precautions for topical and systemic sulfonamides should be observed because of the possibility of absorption. Burning, increased local discomfort, skin rash, urticaria or other manifestations of sulfonamide toxicity are reasons to discontinue treatment.
Dosage: One applicatorful or one suppository intravaginally once or twice daily.
Supplied: Cream—Four-ounce tube with or without applicator. Suppositories—Box of 12 with applicator.

Reconstructive Surgery

QUESTION: What are the indications for referring patients for reconstructive surgery in arterial occlusive disease of the lower extremities?

ANSWER: A patient should be considered a potential candidate for reconstructive surgery if he has severe calf claudication which incapacitates him in carrying out his work or essential activities, if he experiences severe ischemic rest pain in the involved extremity, or if early gangrenous changes have occurred in the foot or toes. Patients with symptoms referable to one or more of these categories comprise the pool of potential candidates for reconstructive arterial surgery. The final selection of any given patient for surgery, however, must await the outcome of a femoral arteriogram. This diagnostic study is done to determine whether or not an adequate distal runoff exists. Although a single open artery is sufficient to proceed with reconstructive surgery, the chances of achieving success will vary directly with the number of patent branches at the popliteal trifurcation.

Some surgeons feel it is permissible to forego a femoral arteriogram in those instances in which amputation is the alternative to a reconstructive procedure. Under these circumstances the runoff distally can be checked at the time of surgery by an arteriotomy in the popliteal artery and by noting the degree of backflow. If backflow is insufficient to permit reconstructive surgery, then amputation is carried out. It is my personal feeling that femoral arteriography should be secured whenever possible, either at the time of surgery or beforehand, to take advantage of the more quantitative information which it can provide.

Montgomery, Alabama

Science

In the middle of the nineteenth century a dogged English mathematician named Shanks computed the value of *pi*, the ratio of the circumference of a circle to its diameter, to 707 decimal places. The job took more than fifteen years. Later mathematicians were content to let Shanks hold the record.

Recently, some mathematical machine operators presented the problem to Eniac, the all-electronic calculator. The machine's 18,800 tubes went into action and computed *pi* to 2,040 places. Time: under twenty-four hours.

Meetings and Announcements

Mayo Clinic Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery will be held at the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Identical sessions are offered on November 3, 4, 5, 1969 and November 10, 11, 12, 1969.

This program is acceptable for credit by the American Academy of General Practice and the College of Family Physicians of Canada. The registration fee for this program is $20.

The number of physicians who can be accommodated is necessarily limited. For this reason identical programs will be offered two successive weeks. The program will be presented first on November 3, 4, 5, and repeated on November 10, 11, 12. Those wishing to attend should communicate with M. G. Brataas, Mayo Clinic, Rochester, Minnesota 55901, indicating which session they would prefer to attend.

Clinical Neurology Fellowships

Fellowships in Clinical Neurology have been established at the Minneapolis Veterans Administration Hospital.

General Practitioners and Non-Neurological Specialists are invited to apply for an intensive postgraduate training experience on the Neurological Wards at the Minneapolis VA Hospital. Programs are designed to provide one to four weeks of supervised bedside and didactic instruction in the diagnosis and treatment of neurological disease. Those accepted for the fellowship may receive quarters, if desired. Fellows may elect any one or a combination of the following programs:

Week 1—The Neurological Examination
Week 2—Special Neurological Diagnostic Procedures
Week 3—Latest Treatments of Acute and Chronic Neurological Problems
Week 4—Frontiers of Neurological Research

Each program will commence on Monday and terminate on Friday.

Apply to Milton Alter, M.D., Ph.D., Chief, Neurology Service, Veterans Administration Hospital, 54th St. and 48th Ave. So., Minneapolis, Minnesota 55417.

Hennepin County Academy of General Practice

The Hennepin County Academy of General Practice is again sponsoring an invitational banquet on Monday evening, November 17, 1969. The affair will be held at the Radisson Hotel at 6:00 p.m. Speaker will be Mr. Harold P. Pluimen. The title of his presentation is, "The Frontiers of Our Times". Contact Donald L. Wright, M.D., 3620 Central Avenue N.E., Minneapolis, Minnesota, Telephone (612) 781-3494.

American Board of Family Practice

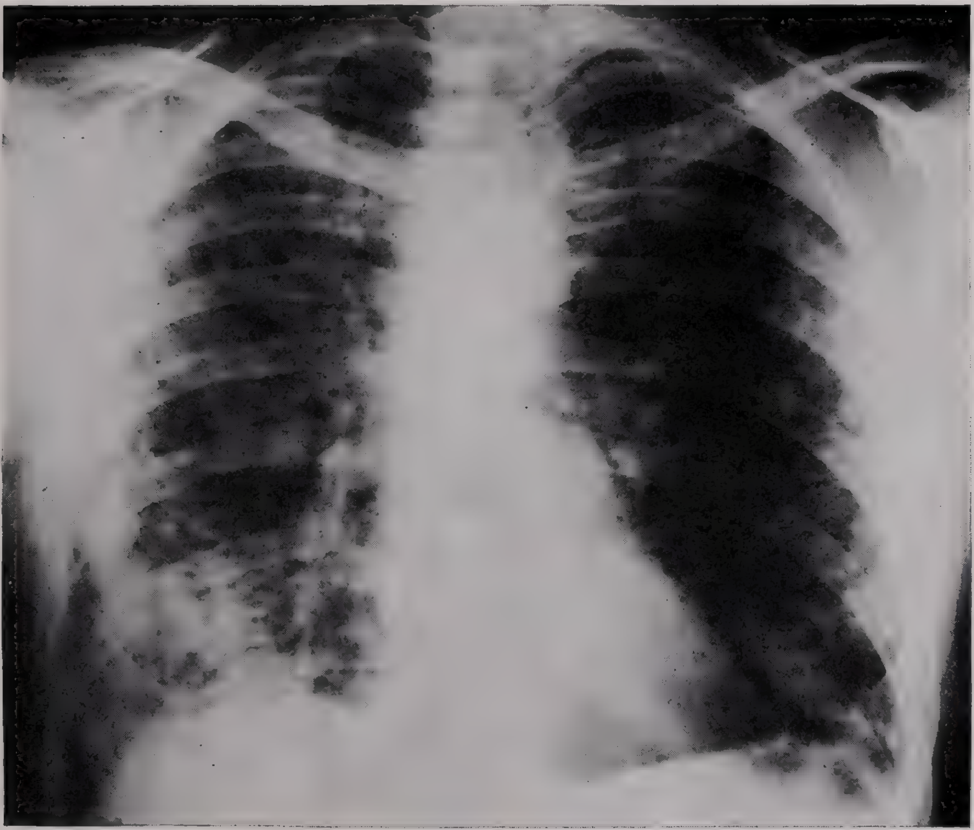
The American Board of Family Practice announces that it will give its FIRST examination for certification in various centers throughout the United States. The examination will be over a two-day period on February 28-March 1, 1970. Information regarding the examination and eligibility for the examination can be obtained by writing: Nicholas J. Pisacano, M.D., Secretary, University of Kentucky Medical Center, Annex #2, Room 229, Lexington, Kentucky 40506.

The Viewing Box

Skin Rash and Abnormal Chest Roentgenogram

THIS IS THE chest film (Figure) of a 22-year-old man who, seven days prior to admission, developed a maculopapular rash on his trunk which soon become vesicular and was accompanied by itching, malaise, dry cough, and pleuritic chest pain.

What is your diagnosis? (See next page.)



Figure

Diagnosis: Chickenpox pneumonia.

The disease varies greatly in severity. At one end of the spectrum it can be severe if not catastrophic and is characterized by dyspnea, hemoptysis, cyanosis, fever, and prostration, while on the other extreme it may be mild, go undetected, and be diagnosed only on x-ray. The disease can be fatal in some cases. Physical findings, even in severe cases, rarely include the classical signs of pulmonary consolidation. Usually there are only coarse breath sounds, occasional rhonchi, expiratory wheezes and tachypnea. Symptoms include cough, hemoptysis, chest pain (50%) of either deep or pleuritic type, dyspnea (50%), fever, and malaise. Laboratory findings are undramatic, consisting of either leukopenia or normal white cell count, occasionally with slight lymphocytosis.

Involvement of the respiratory tract during an episode of chickenpox can be caused by either secondary bacterial invaders or by the chickenpox virus directly. Weinstein and Meade reported a series of 453 patients with chickenpox. Of these, 41 developed respiratory tract infection. Twenty of the 41 were under the age of seven, while 21 were over the age of 19. Children were susceptible to either pure chickenpox or bacterial pneumonitis, the latter most often being caused by *Hemophilus influenzae,* while adults seemed to exhibit exclusively pure viral involvement of the respiratory tract.

X-ray findings: The chest film is characterized by many nodular, rounded infiltrates seen throughout both lung fields. The lesions are variable in size, have indistinct outlines and appear to be concentrated at the lung bases. There is bilateral lymphadenopathy and prominence of the bronchovascular markings. The x-ray changes in the lungs disappear more slowly than the clinical manifestations, some changes persisting up to months or years after symptomatic recovery.

Helmut Behling, M.D.*
Minneapolis, Minnesota

The Golden Age

Devoted physicians also watched over Walt Whitman through the series of cerebral hemorrhages that began in his forties. His Canadian friend Dr. Ralph M. Bucke twice brought the famed Dr. William Osler to see him. Between 1869 and 1888 he suffered four major strokes with paralysis, the last one accompanied by mental confusion and some speech disturbance, but he recovered almost completely from each one, on one occasion after electric stimulation to paralyzed limbs. Autopsy surprised physicians by showing, in addition to longstanding severe cerebral arteriosclerosis, advanced tuberculosis of the lungs and abdomen.*

Editor's Note: Can you imagine William Osler missing a diagnosis like that?

Nose clear as a whistle

(THANKS TO DIMETAPP®)

Dimetapp Extentabs® does an outstanding job of helping to clear up the stuffiness, drip and congestion of colds and upper respiratory allergies and infections. Each Extentab keeps working up to 12 hours. And for most patients drowsiness or overstimulation is unlikely. Try Dimetapp. It clearly works.

FOR UPPER RESPIRATORY ALLERGIES AND INFECTIONS

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

UP TO 12 HOURS CLEAR BREATHING ON ONE TABLET

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

Owner Breaks Arm When Yacht Runs Agroun

Schuyler, Oct. 31. Harry Waters of Covesville incurred a fractured arm … acht … ck a large rock … tially capsized. The fire depart had to rescue Waters by small Damage to the yacht is estima

Hasn't the skipper had enough excitement for one day?

For the patient who has been through an accident, the worry and anxiety following the mishap may actually heighten the perception of pain. This is why there's a classic ¼ grain *sedative* dose of phenobarbital in Phenaphen with Codeine—to take the nervous "edge" off, so the rest of the formula can control the pain more effectively.

A. H. Robins Company,
Richmond, Va. 23220 A-H-ROBINS

Phenaphen® with Codeine

Phenaphen with Codeine Nos. 2, 3, or 4 contains: Phenobarbital (¼ gr.), 16.2 mg. (warning: may be habit forming); Aspirin (2½ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine Phosphate, ¼ gr. (No. 2), ½ gr. (No. 3), or 1 gr. (No. 4) (warning: may be habit forming).

The compound analgesic that calms instead of caffeinates

Indications: Phenaphen with Codeine provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed; Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

Didactic

The Neurological Examination*

THE NEUROLOGICAL examination is a gross but useful tool, without mysticism or ritual. It is a method of challenging the function of the nervous system and/or its parts. If the nervous system meets the challenge of a normal response to a neurological examination it is assumed to be reasonably healthy; if it fails it is likely to be pathological. Authors have devoted much energy and many pages to describing the subtleties and endless techniques of the examination until many are convinced that it is an impossible task. The purpose of this paper is to dispute this impression. Much information is available from the neurological examination and all practitioners are fully able to perform and interpret it most adequately in their practices.

Organ Function

We should always start our neurological examination by challenging the "organ function:" the total brain function consisting of awareness of time, place, person and changes in the environment. Decompensation of this function results in disorientation, confusion or coma.

Orientation

The most clinically useful "organ function" is orientation, and it is the most frequently neglected sign. The individual who errs in his orientation of time, place or person has significant diffuse involvement of his entire brain. Less extensive diffuse pathology of the entire brain manifests as impaired memory, either recent or remote, impaired judgment and impaired mental capacities.

Focal Pathology

Each brain hemisphere contains a motor, a sensory, and a visual function and, uniquely to the left hemisphere is the speech function.

Frontal Lobe

The anterior 70% of each hemisphere is the frontal lobe which has a motor function. Pathology here manifests as a contralateral upper motor neuron deficit of the face and/or the extremities. A central seventh paresis, a loss of a nasolabial fold and a slight loss of mobility of the facial musculature below the eye, or a minimal motor deficit of the twelfth cranial nerve with slight deviation of the protruded tongue away from the side of the lesion suggests a lesion involving the corticobulbar tracts of the frontal lobe. A loss of volitional movement, a hyperreflexia, an increase in tone (spasticity), a sustained or unsustained clonus or the appearance of asymmetric pathological toe signs on one side signifies pathology within the contralateral corticospinal tracts of the frontal lobe.

Thalamoparietal Region

The thalamoparietal region of the hemisphere functions to permit awareness of sensory stimuli from the contralateral side of the body. Pathology here results in a loss of awareness of sensory appreciation. Lesions within the thalamus produce a hypalgesia and hypesthesia of the contralateral side of the body and face often including the cornea, and the pharyngeal wall. The deficit may be gross as compared to the more normal side or it may be subtle, manifest only as a neglect of the side when simultaneous bilateral stimulation is performed.

Parietal Cortex

The function of the parietal cortex is to reach conclusions. Pathology here may make it impossible for the brain to utilize the sensory cues of the size, shape, texture and weight of an object in order to identify it correctly. This is how we utilize astereognosis.

---

*Presented before the Minnesota Academy of General Practice Convention, Hotel Radisson, Minneapolis, Minnesota.

Occipital Lobe

Posteriorly the occipital lobe receives fibers from the eye via the thalamus which carry visual cues. Pathology involving these fibers (geniculo-calcarine tract) results in an impaired appreciation of visual clues entering the eye from the opposite side of the body. A lesion involving the temporal lobe portion of these radiations results in blindness to cues from the contralateral superior quadrant of each field of vision. A lesion of the parietal lobe may result in blindness to cues from the inferior quadrants. A lesion of the geniculate portion of the thalamus or at the occipital pole produces blindness from the entire contralateral half of visual fields of each eye. These deficits can be easily determined on tangent screen examinations and their pattern permits precise localization of pathology.

Speech Center

Speech is the fourth clinical function of the brain and is uniquely vulnerable in the left hemisphere alone, especially the posterior one half. Lesions within the left hemisphere produce aphasia. Lesions posterior in the temporoparietal-occipital region may impair the appreciation of the spoken word or the formulation of appropriate speech. Appreciation of simple directions may be lost; or the ability to recognize and name objects, words, figures and body parts correctly is lost. Speech produced, though erroneously, is not appreciated by the brain and there may be no effort to correct it. Lesions more anterior in the isthmus of the temporal lobe or the frontal lobe speech center may result in near total inability to speak, a deficit so recognizable by the brain that the patient manifests obvious severe frustration. Hence normal or abnormal speech tells us much about the state of the brain.

Cerebellar Structure

Coordination

Another important function, coordination, is vulnerable in the cerebellar structure. Lesions within the mesial structure produce a staggering, inebriated gait characterized by the feet being placed wide apart; sudden turns are unsteady. These signs appear when pathology develops in this portion of the cerebellum. Other than the primary function of maintaining a coordinated upright gait, the cerebellar hemisphere coordinates the movements of the arms and hands. Pathology here causes gross tremor near the completion of a motor act of the ipsilateral hand (an intention tremor) seen as the hand tries to touch the nose. Lesions here impair the ability of the extremity to measure its movements accurately and result in "past pointing" or "overshooting the mark" on attempted tasks. The capacity to do rapidly alternating movements of the ipsilateral hand may be impaired from pathology in this portion of the cerebellar system.

Brain Stem

Midbrain—Pons

The brain stem of man is a very small structure that controls the muscles of the face and head region. The functions of the brain stem express themselves externally on the ipsilateral side and are discretely manifest in movements that are simple to test. The function of the midbrain from a clinical standpoint is movement of the ipsilateral eyeball upward, downward and nasally. The pons' functions are to close the jaw, turn the ipsilateral eye laterally, and move the facial muscles. A manifest unilateral deficit of lateral rotation of the eye, of contraction of the masseter muscle or the facial musculature is evidence of pathology within the ipsilateral pons.

Medulla

The function of the medulla, the lowest portion of the brain stem, is to permit swallowing and speaking, movement of the tongue and regulation of the cardiorespiratory rate. Focal pathology within this structure manifests as an ipsilateral flaccid paresis of the palate or atrophy and paresis of the tongue. The vital regulatory functions of heart and respiration are less vulnerable and clinically of little significance in the neurological examination.

Basal Nuclei

The extra-pyramidal functions of motor tone and movement regulation come from the deep midline paired basal nuclei. Abnormal movement of choreic, athetoid,* ballistic, dystonic or tremor type warrants the conclusion that these structures are pathologically involved. "Cogwheel" rigidity is produced by pathology in these same structures.

Spinal Cord

The spinal cord functions as a simple carrier of information to and from the higher centers. It is also the origin of the final common pathway to the musculature of the body and organs. This final common pathway originates in the anterior horn cell column which has a reliable longitudinal distribution in relation to body musculature. Each level of the cord innervates a definite muscle group in a way which permits the neurological examination to localize precisely within it.

Upper Three Cervical Segments

The function of the upper three segments of the cervical cord is flexion of the chin upon the chest; loss of the sternocleidomastoid mass or power on one side denotes pathology of the ipsilateral cord at that level.

Fourth Cervical Segment

The function of C_4 level is control of the diaphragm; its paralysis with a resultant loss of cough is a manifestation of pathology at this level.

Fifth and Sixth Cervical Segments

The function of C_5–C_6 is to innervate the biceps of the ipsilateral arm; flaccid paresis or atrophy of this muscle pointedly suggests pathology of the cord.

Seventh and Eighth Cervical Segments

C_7 functions to flex and extend the wrist; a loss of these functions alone localizes the pathology to that level. Cervical levels 7 and 8 distribute to the triceps of the ipsilateral arm; loss of elbow extension power or atrophy, fasciculations or hypoflexia of that muscle warrants the conclusion of pathology at that level. The levels of C_8–T_1 function to give us power of hand grasp; pathology at that level results in a loss of grip.

Summary

Thus the purpose and partial technique of the neurological examination as herein outlined constitutes a method of evaluating the status of the central nervous system by challenging the various functions of the parts. A few very simple tests give us much useful information and permit us to derive accurate conclusions about the health or disease of the nervous system.

Donald A. Scholz, M.D.

Dr. Scholz is a consultant in internal medicine on the staff of the Mayo Clinic where he subspecializes in endocrinology.

The photograph of Taxco, Mexico, was taken in August, 1968, from a vantage point which looks down on the city and across the valley.

Dr. Scholz was a snapshot winner in the Annual Minnesota Sunday Tribune contest in 1963, with a certificate of merit from the National Newspaper Contest when the picture was submitted that same year.

Selfishness

A farmer imported some especially fine seed-corn and produced a crop that was the envy of his neighbors. When they sought some of the seed, he refused, fearing to lose the competitive advantage he had gained. The second year his crop was not so good; the third year, results were even worse. Suddenly, it dawned upon him that the poor-grade corn of his neighbors was pollinating his prize corn. His selfishness had caught up with him.

ABDOMINAL ADENOVIROSIS AND APPENDICITIS

Doctors Bonard and Paccaud[1] have demonstrated adenoviruses in appendices and in abdominal lymph nodes of patients with mesenteric adenitis. These patients, who ranged in age from two to 22 years, had a laparotomy for acute appendicitis. The authors studied 158 specimens: 26 appendices, 59 lymph nodes, and 73 mixed specimens made up of an appendix and an abdominal lymph node. All specimens were minced and cultured on coagulated chick plasma medium. Adenoviruses were isolated from 11.7 per cent of the appendices, 3.8 per cent of the lymph nodes, and 17.7 per cent of the mixed specimens. Types I, II, and VII adenoviruses were cultured out. Feces cultures yielded no viruses.

Microscopically, two appendices showed acute inflammation, whereas the others exhibited chronic, slight inflammation to none. All lymph nodes were swollen and showed adenitis (hyperplasia). Bonard and Paccaud divide mesenteric lymphadenitis into two phases. Phase I is characterized by acute abdominal pains and signs of recent viral disease (upper respiratory tract); it may or may not be complicated by an acute appendicitis. During this phase of viremia lymph follicles of the ileum, appendix and mesentery lymph nodes may become infected. The complement fixation test is positive and isolation of adenoviruses can be accomplished. Phase II is characterized by chronicity. The adenoviruses remaining in the cells elicit no detectable immunological reaction. Abdominal virus adenitis should be considered when a patient presents the following syndromes: pharyngitis, even mild, pains in the right iliac fossa, either chronic or acute with an exacerbation, contemporary to the pharyngitis.

Of 15 patients studied by Bonard and Paccaud, seven complained of abdominal pain of varying intensity for several weeks previous to hospitalization. In eight patients, the onset was acute and indistinguishable from acute appendicitis. Because of the clinical difficulty of distinguishing between these two clinical entities, Bonard and Paccaud recommend that all patients with acute right fossa pains should have a laparotomy whether or not they have a recent history of a viral infection. They advance the postulate that inflammatory lesions in the submucosa may play a role in certain types of acute appendicitis. As long as the mucosa is intact, the appendix may be only slightly hyperemic. When the mucosa is destroyed, however, bacterial superinfection may occur, resulting in an acute appendicitis.

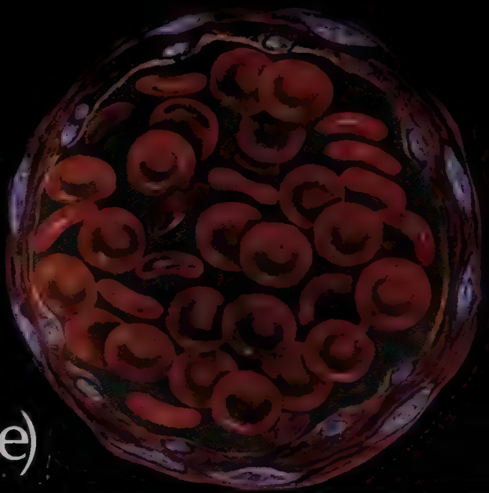
Roniacol® Timespan®
(nicotinyl alcohol tartrate)



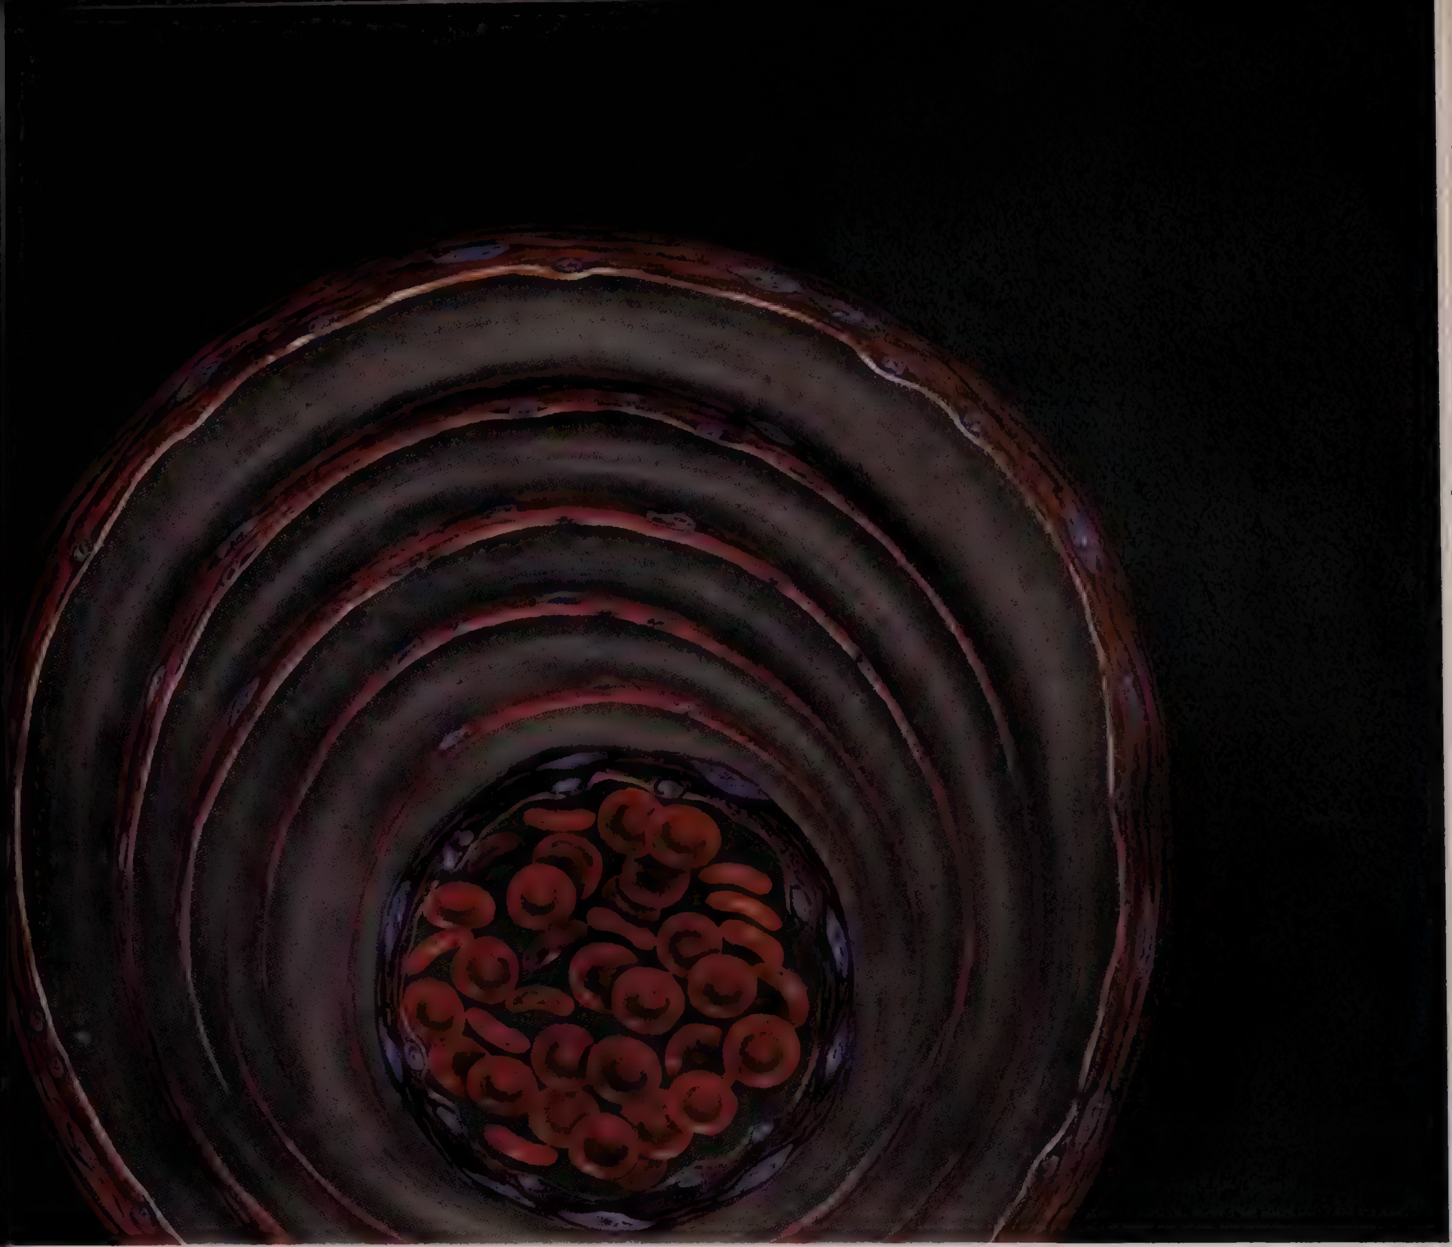
Because peripheral vasodilatio is needed now... and must often be continued

Roniacol Timespan (nicotinyl alcohol tartrate) can make a significant contribution to effective treatment of peripheral vascular disorders. It is directed specifically toward improvement of peripheral blood flow, relief of ischemic symptoms, and the long-term management of these conditions.

Specific pharmacologic action—Roniacol (nicotinyl alcohol) acts selectively by relaxing smooth muscle of peripheral blood vessels. Onset of action is smooth and gradual, rarely causing severe flushing.

Relative freedom from side effects—Side effects that may occur occasionally with Roniacol seldom require discontinuation of therapy

Prolonged, continuous drug release—Prolonged peripheral vasodilation is provided sustained-release Roniacol Timespan (nico alcohol tartrate) Tablets. Part of the drug b comes available immediately, the remaind continuously over a period of up to 12 hou and dilation of constricted peripheral vess usually maintained. Thus, with a single dos medication, patients can enjoy the benefit increased peripheral blood flow in ischem extremities for up to 12 hours.



mooth peripheral vasodilation from initial losage...extended with imple, well-tolerated, b.i.d. dosage

e prolonged action of Roniacol Timespan icotinyl alcohol tartrate) together with its her benefits offer a therapeutically practical easure in the long-term management of ripheral vascular disease—advantages pecially important for older patients.

fore prescribing, please consult complete oduct information, a summary of which lows:

dications: Conditions associated with ficient circulation; e.g., peripheral vascular ease, vascular spasm, varicose ulcers, cubital ulcers, chilblains, Meniere's syn- ome and vertigo.

Caution: Roche Laboratories endorses caution in the administration of any therapeutic agent to pregnant patients.

Side Effects: Transient flushing, gastric disturbances, minor skin rashes and allergies may occur in some patients, seldom requiring discontinuation of the drug.

Dosage: 1 or 2 Timespan Tablets—150 mg nicotinyl alcohol in the form of the tartrate salt—bottles of 50 and 500.

Preludin® phenmetrazine hydrochloride
Preludin is indicated only as an anorexigenic agent in the treatment of obesity. It may be used in simple obesity and in obesity complicated by diabetes, moderate hypertension (see Precautions), or pregnancy (see Warning).

Contraindications: Severe coronary artery disease, hyperthyroidism, severe hypertension, nervous instability, and agitated prepsychotic states. Do not use with other CNS stimulants, including MAO inhibitors.

Warning: Do not use during the first trimester of pregnancy unless potential benefits outweigh possible risks. There have been clinical reports of congenital malformation, but causal relationship has not been proved. Animal teratogenic studies have been inconclusive.

Precautions: Use with caution in moderate hypertension and cardiac decompensation. Cases involving abuse of or dependence on phenmetrazine hydrochloride have been reported. In general, these cases were characterized by excessive consumption of the drug for its central stimulant effect, and have resulted in a psychotic illness manifested by restlessness, mood or behavior changes, hallucinations or delusions. Do not exceed recommended dosage.

Adverse Reactions: Dryness or unpleasant taste in the mouth, urticaria, overstimulation, insomnia, urinary frequency or nocturia, dizziness, nausea, or headache.

Dosage: One 25 mg. tablet b.i.d. or t.i.d. Or one 75 mg. Endurets tablet a day, taken by midmorning.

Availability: Pink, square, scored tablets of 25 mg. for b.i.d. or t.i.d. administration, in bottles of 100 and 1000.
Pink, round Endurets® prolonged-action tablets of 75 mg. for once-a-day administration, in bottles of 100 and 1000.
(B)R3-46-560-B

Under license from Boehringer Ingelheim G.m.b.H.

For complete details, please see full prescribing information.

Geigy Pharmaceuticals
Division of Geigy Chemical Corporation
Ardsley, New York 10502

For some, obesity can be a serious complication of moderate hypertension, diabetes, or pregnancy.

Preludin may be used to curb appetite in obesity associated with such conditions.
For use during pregnancy, please consult Warning paragraph. The use of Preludin in moderate hypertension should be accompanied by caution. In diabetes, the drug does not increase insulin requirements (requirements may be reduced as weight is lost).
One 75-mg. Endurets tablet taken between breakfast and midmorning will usually provide daylong and early-evening suppression of appetite.

Preludin® phenmetrazine hydrochloride **Endurets®** prolonged–action tablets

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

IMMEDIATE OPENING: Internist or General Practitioner to join six man multispecialty group in northeastern Wisconsin. Excellent professional opportunity to practice in a friendly community, only two actively practicing physicians (General Practitioners) in the community outside of our clinic. Salary commensurate with training and experience first year and then full partnership. Ideal, safe small city living for the family on scenic Lake Michigan with excellent fishing, boating and hunting. All this and still only 1½ hours drive to Milwaukee or 45 minutes to Green Bay or lovely Door County. For complete details contact Robert E. Myers, M.D., Garfield at 23rd, Two Rivers, Wisconsin 54241.

Fracture Conference

Some Complications of Hip Fractures*

Joseph M. Janes, M.D.:†

The first case is that of a 46-year-old woman who came to the Mayo Clinic on January 10, 1968. She had fractured the left femoral neck in June of 1967 and, although she had been allowed partial weight-bearing at home, she continued to have pain (Figure 1). The lateral roentgenogram in this case showed that the nail was not in the neck. The neck of the femur had been partially absorbed. I thought the femoral head might be viable, and I considered doing a McMurray osteotomy (Figure 2), but some of my colleagues thought that the femoral head was probably not viable. At operation it appeared not to be. What would your impression be in this case?

---

*Fracture Conference, June 17, 1968.
†Section of Orthopedic Surgery.

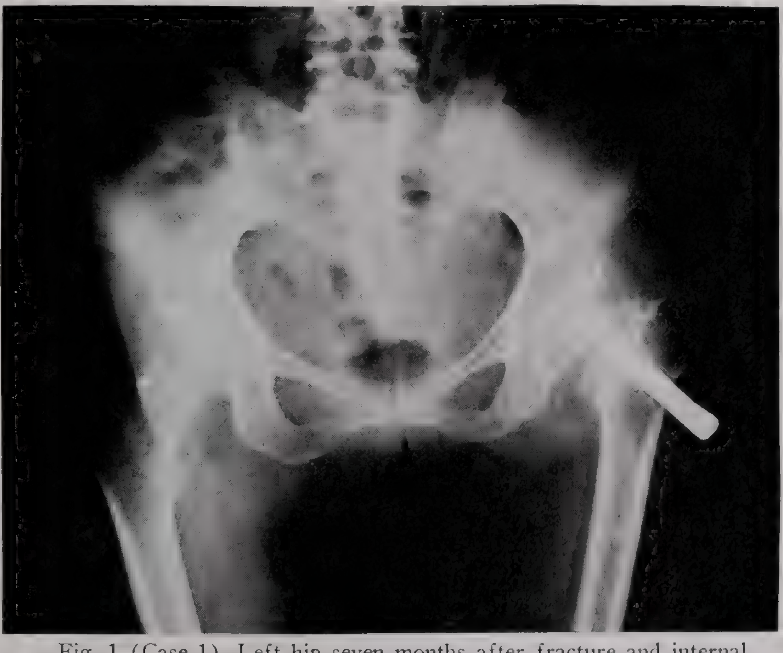

Fig. 1 (Case 1). Left hip seven months after fracture and internal fixation. There is nonunion of fracture. Head of femur is loose, and neck has slipped anteriorly and superiorly.

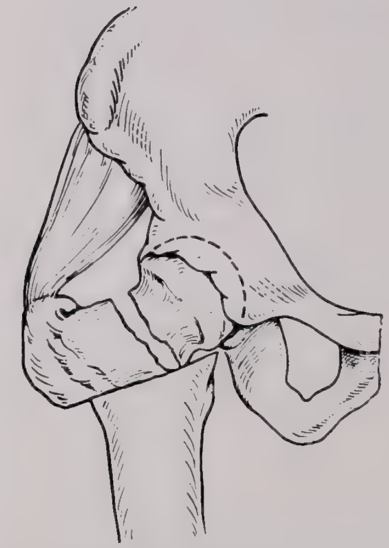

Fig. 2. McMurray osteotomy. (From Colonna, P. C.: Regional Orthopedic Surgery. Philadelphia, W. B. Saunders Company, 1950, p. 326. By permission.)

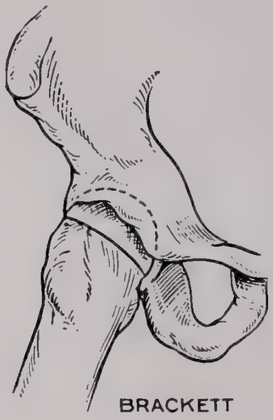

Fig. 3. Position after Brackett procedure. (From Colonna, P. C.: Regional Orthopedic Surgery. Philadelphia, W. B. Saunders Company, 1950, p. 327. By permission.)

Patrick J. Kelly, M.D.:*

Well, let us take the point of view that maybe all femoral heads are not viable when there is no union in such a fracture; if you could trim enough dead bone away from the head, you could then do a Brackett procedure (Figure 3) which I have done in one or two cases in which the femoral head did not bleed well at operation. The patients have subsequently done quite well.

Dr. Janes:

Has the Brackett procedure been compared with the Austin-Moore procedure for this type of thing?

Dr. Mark Coventry:*

No. Dr. Donald Webb and I have just gone over the cases in which I have done the Brackett operation, and the Moore prostheses have been pretty well evaluated. I do not think we could ever come up with a reliable comparison of the two. Age, general health, the amount of femoral neck remaining and the general appearance of the head—all of these points and others make each problem an individual one. I think this might be a better case for a Brackett procedure than for an osteotomy because of the lack of a femoral neck and because of the peculiar change inferiorly on the medial surface. Also, one hates to put a prosthesis in a 46-year-old person.

Dr. Janes:

I have not done so many prostheses for patients less than 50 years old, but we did, in fact, use a prosthesis in this case (Figure 4). I think the Brackett procedure is a technically more complex operation than inserting a prosthesis.

Dr. Janes:

The patient came back to see us in April, at which time she was allowed to bear weight with the support of a cane. She had no pain.

Einer W. Johnson, Jr., M.D.:*

Perhaps, Dr. Janes, it should be said that, although you did not know in this instance whether the head was viable, you decided to do the prosthesis, and at the time of operation you found that the head was not viable. As a routine, what would you think about doing tomograms, assuming, as in the previous case, that we do not know if the head is dead or alive? What is your view on tomograms?

---

*Section of Orthopedic Surgery.

Dr. Janes:

That is exactly what we did in the next case.

Viability of the Head

A 68-year-old woman slipped and fell in December 1966. At her home hospital she had the fixation shown in Figure 5. She continued to have pain.

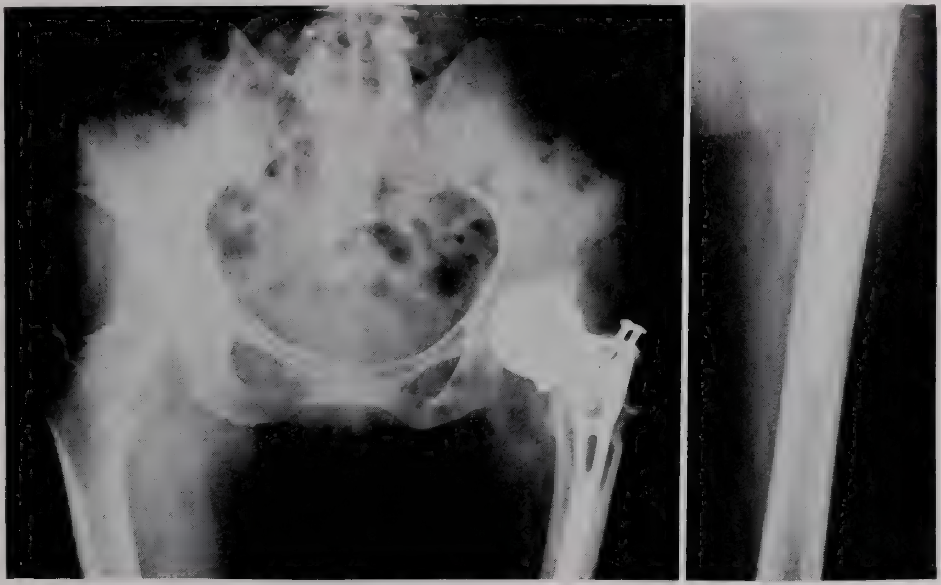

Fig. 4 (Case 1). Three months after removal of nail and insertion of prosthesis.

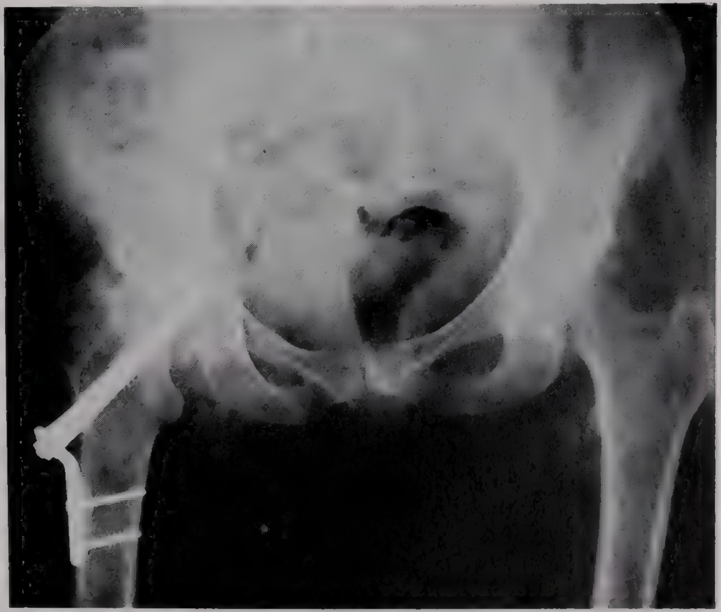

Fig. 5 (Case 2). One year after fracture and internal fixation of right hip. Note collapse of neck, penetration of acetabulum, and resorption about nail. Plate prevents nail from backing out despite resorption.

One can see that she had a graft as well as the fixation. Bone for the graft apparently had been taken from the femur just below the shank of the nail. Thus, the surgeon in this case was trying to take every precaution to prevent what happened. I think the nail would have been fine without the shank which may have been responsible for the pain in the groin that actually brought the patient to us.

Dr. Coventry:

I think part of the head is avascular. Dr. Kelly and I apparently disagree a little on this, but I do not think one could say the *whole* head is vascular or the *whole* head is not vascular. I think the point in the superior aspect of the femoral head is avascular, and I think the point adjacent to the nail and inferior is vascular.

Dr. Janes:

Thank you. We had tomograms in this case (Figure 6). They reportedly showed "no convincing evidence of nonunion" and "no evidence of avascular necrosis."

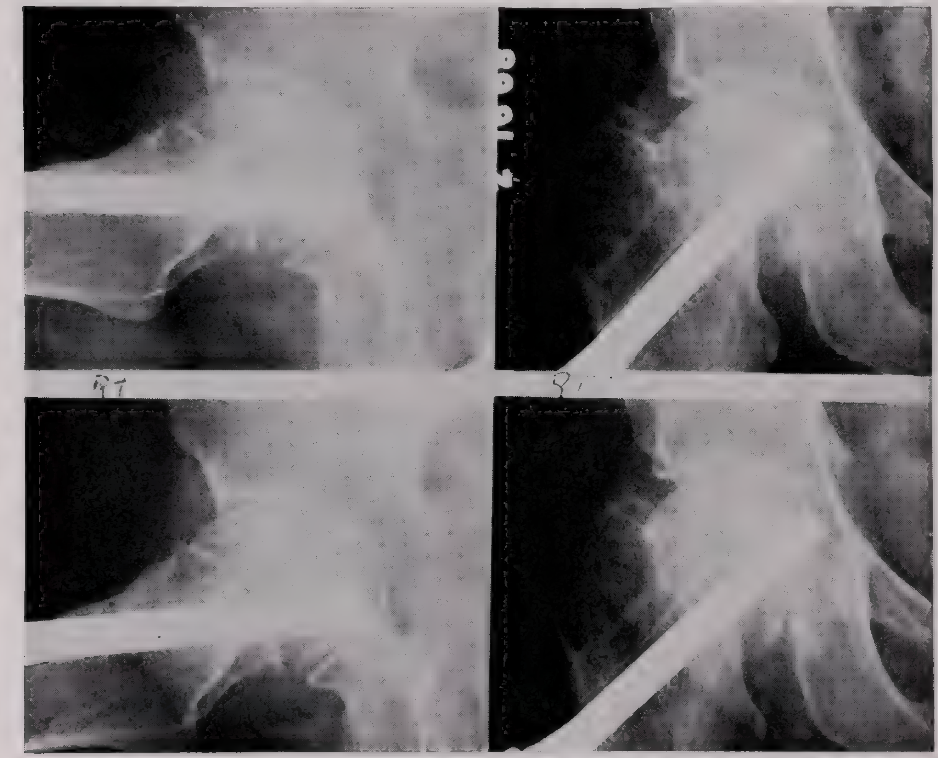

Fig. 6 (Case 2). Tomograms showing no definite evidence of avascular necrosis or nonunion.

Dr. Coventry:

The conical area that I pointed out certainly shows beautifully on the tomograms.

Dr. Janes:

Dr. Johnson, do the tomograms help you in this instance?

Dr. Johnson:

Yes. I agree with Dr. Coventry; I think the femoral head is half dead and half alive.

Dr. Coventry:

One third and two thirds?

Dr. Janes:

I thought she might do well because the roentgenologic report said that there was probably union and no convincing evidence of avascular necrosis.

Dr. Janes:

I took out the internal-fixation nail and found avascular necrosis right where the graft was (Figure 7). A prosthesis was substituted (Figure 8) and the patient is now at home using crutches. She is to avoid weight-bearing for three months.

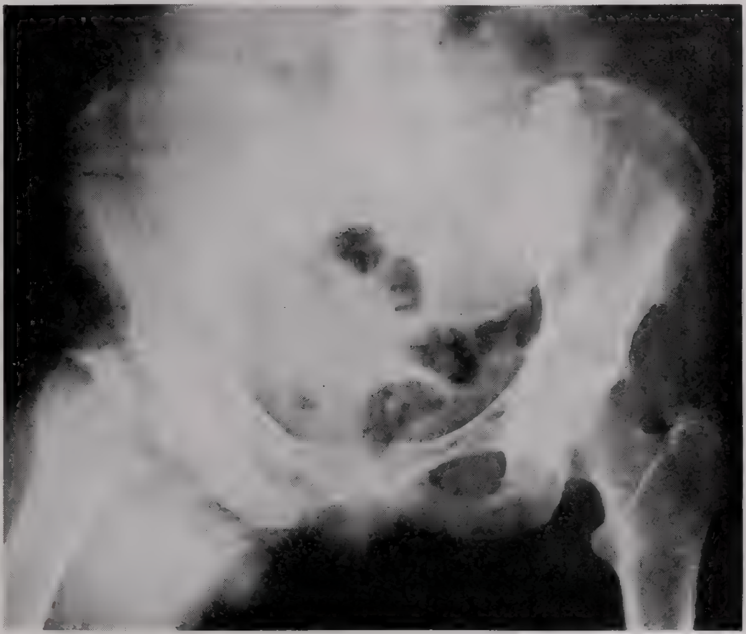

Fig. 7 (Case 2). Obvious nonunion. Femoral head appears to be necrotic.

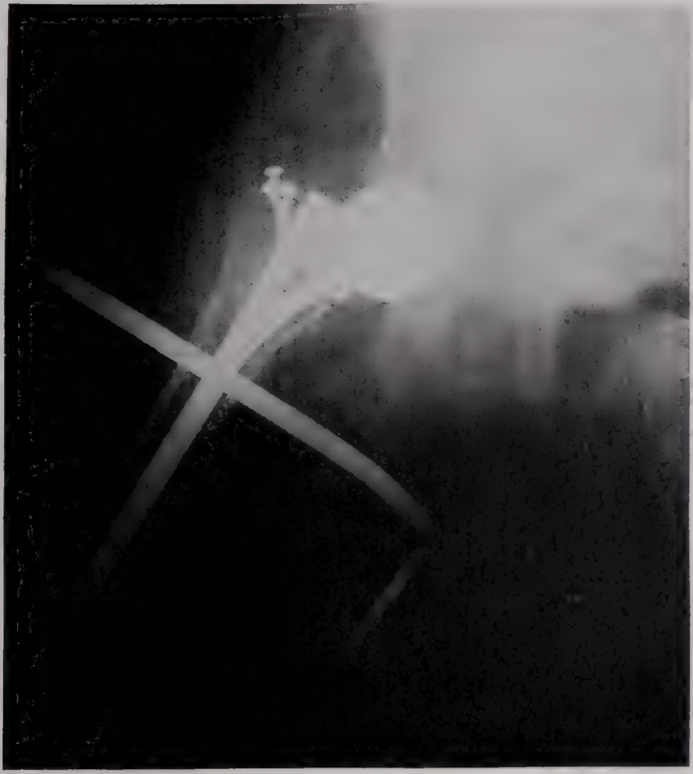

Fig. 8 (Case 2). After insertion of prosthesis.

Dr. Coventry: Dr. Janes, what did you think about the vascularity of the head when you took it out?

Dr. Janes:

It was mainly avascular. There were some bleeding areas, but the most avascular part was that where the cortical bone graft had been applied—which is not supposed to be the case.

From a practical standpoint, however, if there is any avascular necrosis at all, is that not all you need?

Dr. Coventry: That depends on where it is. Certain small areas of avascular necrosis will not interfere with function and may even regenerate and revascularize in time. Unfortunately, it is usually the superior weight-bearing surface that is avascular and that is just the part one does not want affected.

Persistent Pain

Dr. Janes:

The next case concerns a 66-year-old woman who tripped on a rug in church and fractured her right hip in October 1964. Knowles' pins were inserted and a year later were removed. The patient had persistent pain and had not walked without support since the fracture. In October 1966 she had an operation elsewhere for the insertion of a prosthesis (Figure 9). An acetabuloplasty was done at the same time. The patient continued to have pain and came here in February 1968. She was on crutches and unable to bear weight on the right foot.

Dr. Coventry: Marked osteoporosis is surely evident.

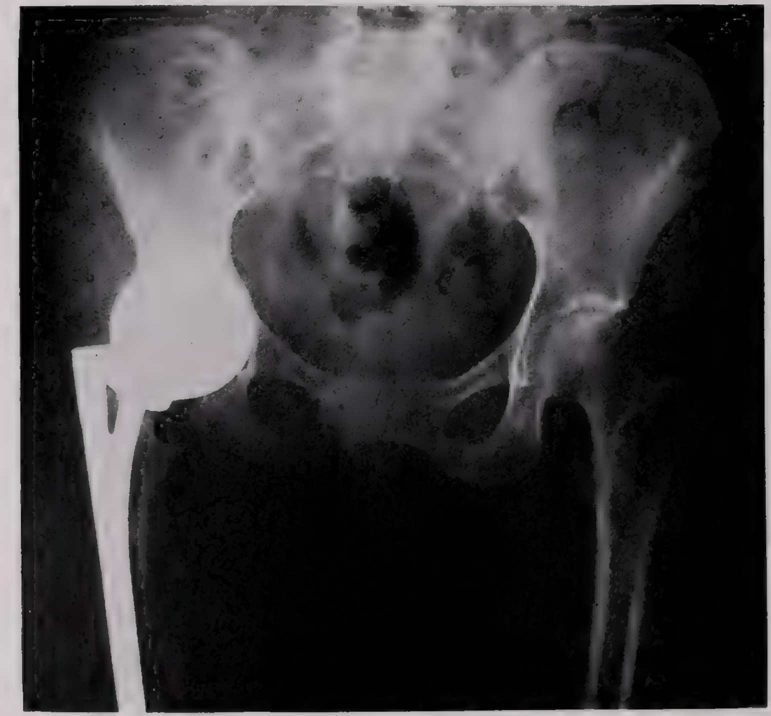

Fig. 9 (Case 3). Appearance of prosthesis for right hip one and three-quarters years after its insertion.

Emanuel Semerad, M.D.:*

The prosthesis is extremely large. The inner wall of the acetabulum has remodelled itself around the prosthesis.

Dr. Janes:

One cause of a painful hip is too large a head on the prosthesis. I cannot quite explain why that is; the lady said she had the acetabulum reamed out so they could put that in. Can you tell me another cause of pain in the hip associated with a prosthesis?

Ray E. Santos, M.D.:*

Dislocation could be another cause. Infection is another; loose prosthesis is another.

Dr. Janes:

Another one?

Allen P. Schlein, M.D.:*

Retroversion or anteversion of the head of the prosthesis.

Dr. Janes:

I think there is a large group where everything looks fine and the roentgenograms look good, but the patient has pain.

Dr. Coventry:

There is another circumstance called the "sinking" prosthesis and it is just the opposite of the acetabular-protruding prosthesis. Instead of going up into the pelvis, it sinks down the shaft of the femur.

Dr. Janes:

If this prosthesis is not quite right, do you think putting another prosthesis in is the answer?

Dr. Schlein:

I think you would probably run into trouble with another one. This one is nowhere near the size of the opposite femoral head. This looks massive. I

---

*Resident in Orthopedic Surgery.

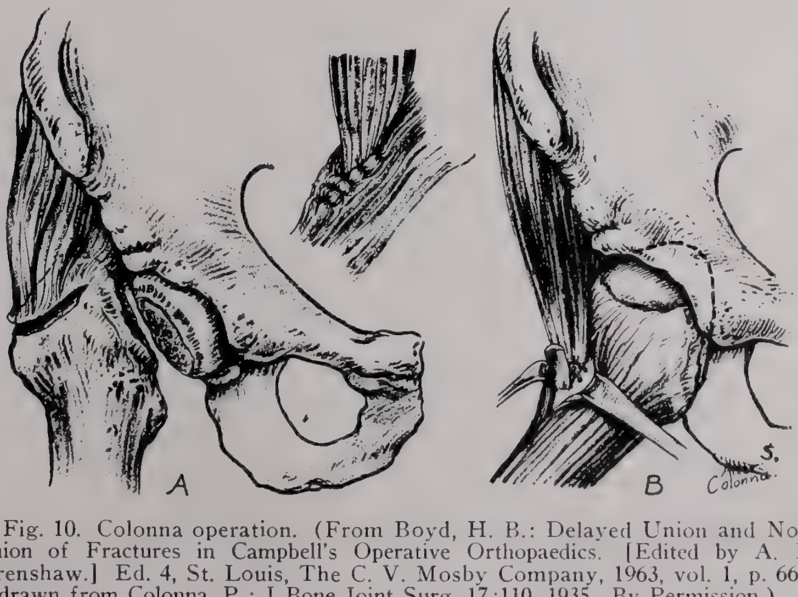

Fig. 10. Colonna operation. (From Boyd, H. B.: Delayed Union and Nonunion of Fractures in Campbell's Operative Orthopaedics. [Edited by A. H. Crenshaw.] Ed. 4, St. Louis, The C. V. Mosby Company, 1963, vol. 1, p. 669; redrawn from Colonna, P.: J Bone Joint Surg. 17:110, 1935. By Permission.)

do not think another prosthesis is the answer. I think you have to do one of the other procedures. I would hate to tell you to arthrodese this hip for a 66-year-old woman, but at least you could get rid of her pain by this operation.

Dr. Janes:

This is one of the procedures that we considered—to put bone grafts around the hip prosthesis. We also thought of the Colonna procedure and finally, after much soul searching, we did a Colonna operation (Figures 10 and 11). We left the patient in the cast six weeks, kept her in bed another week or so and encouraged her to mobilize on her own. She was relieved of her pain and dismissed on crutches with instruction to have a lift put on her shoe. I recently heard from her doctor, and he said that she still has no pain.

Dr. Coventry:

We have had about 12 dislocations of the prosthesis in our series. In the Colonna procedure the lesser trochanter acts as a fulcrum against the side of the pelvis if the acetabulum is too high, as it was here. The Colonna procedure is a much better operation than a pure Girdlestone (Figure 12)—if you

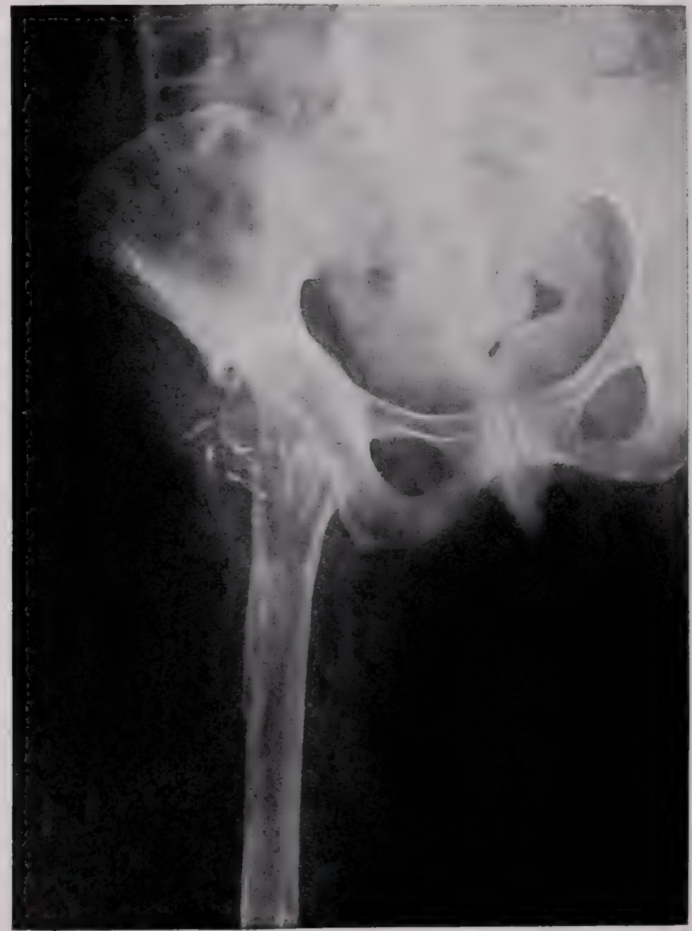

Fig. 11. (Case 3). Two months after removal of prosthesis and Colonna reconstruction of hip.

can get by with it—because there is less shortenting, and one has stability.

Infection

Dr. Janes:

Our next case is that of a 66-year-old woman who fell on the ice and fractured her hip in December 1957. The fracture was nailed in her home community. The nailing failed, and a prosthesis was inserted in June 1958. Two months later purulent material drained from the hip and continued as a sinus until April 1963 when incision and drainage was done; but drainage resumed. The patient came to this clinic in October 1963. The prosthesis was in place (Figure 13), but she complained of a painful hip. We removed the loose prosthesis, which we thought was promoting further drainage, and did a Colonna procedure (Figure 14); and her wound was packed open until it healed from the base. The patient was in a cast for six weeks and later dismissed on crutches. She came back here in May 1964 with no drain-

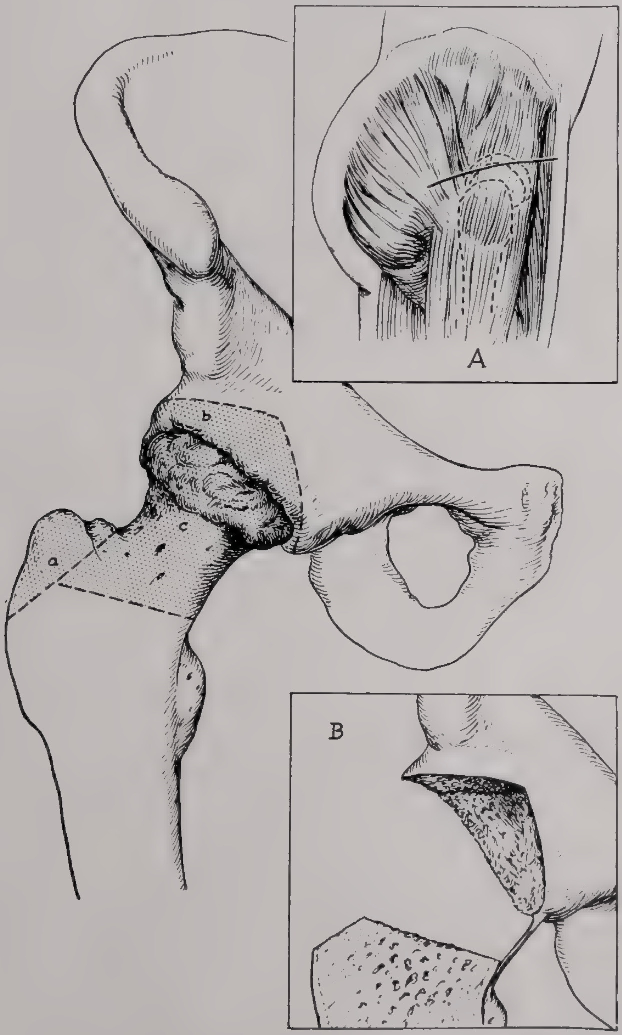

Fig. 12. Girdlestone operation. (From Waring, T. L.: Acute Infectious Arthritis and Wounds of Joints. In Campbell's Operative Orthopaedics. [Edited by A. H. Crenshaw.] Ed. 4, St. Louis, The C. V. Mosby Company, 1963, vol. 1, p. 847. By permission.)

age. Roentgenograms taken then show that if the head had not dislocated it certainly was on the edge of the acetabulum (Figure 15).

Dr. Johnson:

What about her pain? Did she get an acceptable range of motion?

Dr. Janes:

She did not get return of a full range of motion, but she lost most of her pain. She was happy. I suppose we could have treated the infection by continuous suction and by using irrigation tubes rather than packing the wound open.

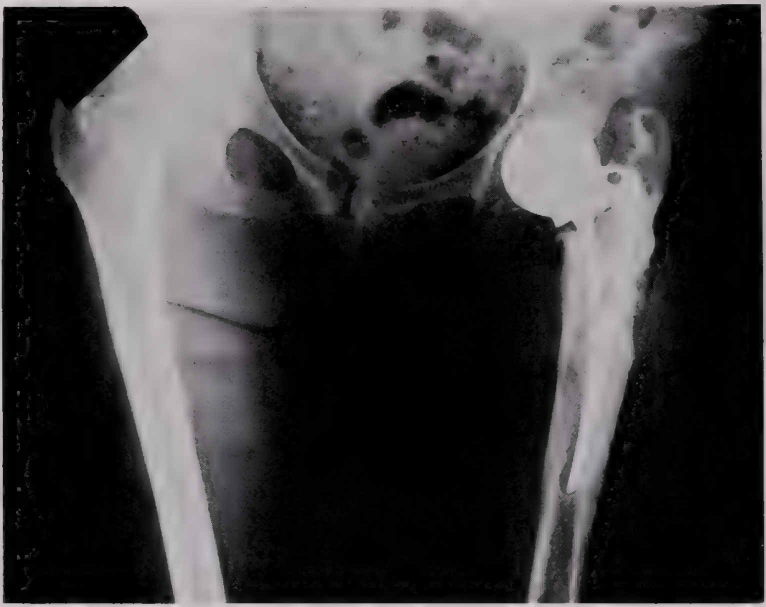

Fig. 13. (Case 4). Five years after insertion of prosthesis for nonunion of fracture of left hip. Note resorption of bone about stem of prosthesis and wide joint space.

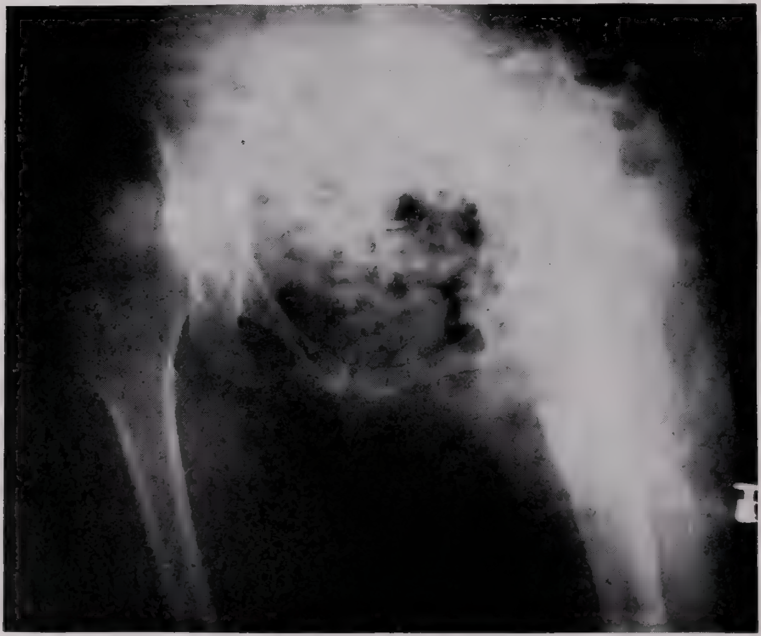

Fig. 14. (Case 4). One month after removal of prosthesis and Colonna reconstruction of hip.

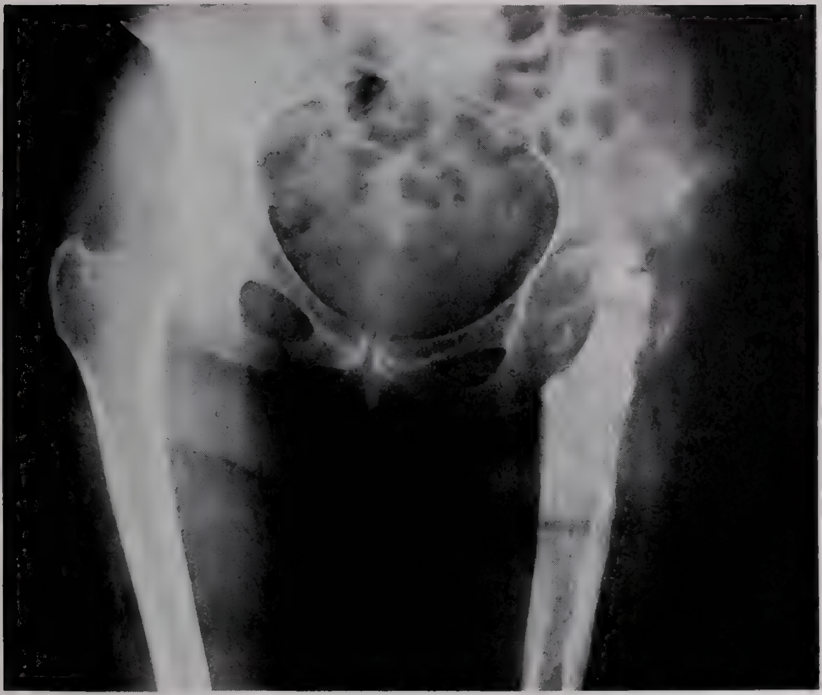

Fig. 15. (Case 4). Partial dislocation seven months after Colonna operation.

Wobble of the Prosthesis

Dr. Janes:

The last case is that of a 62-year-old woman who complained of a painful hip when she came to this clinic in November 1967. She had been operated on by one of our former residents. He had used a staple to hold a portion of the trochanter in place (Figure 16). She gave the history that postoperatively, while she was in a department of physical medicine elsewhere, she slipped and injured her hip. Whether this has any significance, I do not know. Would someone venture to say why this hip was painful?

Dr. Noel T. Van Ness:*

She has very little femoral neck left, which could cause some problems. I get the impression that there is an area of resorption around the end of the prosthesis which would indicate that it was loose.

Dr. Janes:

The diagnosis was made a little easier in this case because the patient said that when she put her weight on this leg she could feel something clicking in her hip.

I have usually gone on the principle that if one prosthesis has failed there is not much reason to believe that a new prothesis will do any better. But that is probably not a completely valid assumption, especially if it is a longer-stemmed prosthesis which we have available now. In this case, we did insert a different type of prosthesis (Figure 17), but we also did something else. We inserted iliac grafts to further strengthen the area of contact of the prosthesis. This patient was last seen in March 1968. I think you can observe that the iliac grafts appear to have consolidated (Figure 18).

---

*Resident in Orthopedic Surgery.

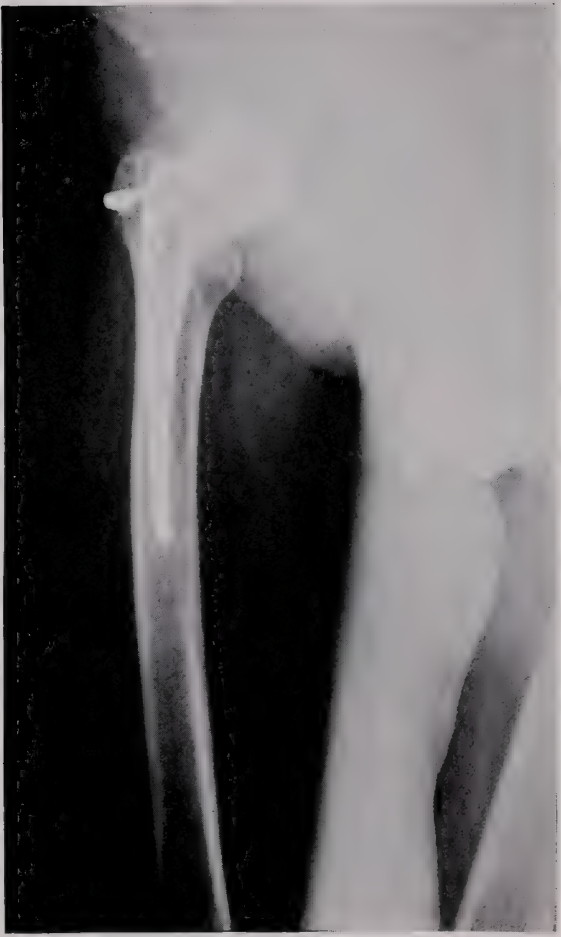

Fig. 16. (Case 5). Resorption of bone about stem of prosthesis of right hip one and a half years postoperatively.

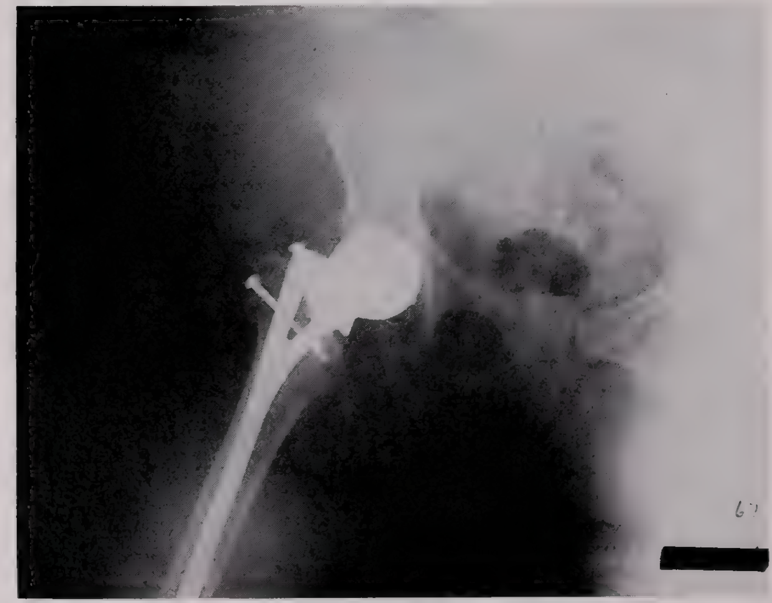

Fig. 17. (Case 5). After insertion of Matchett-Brown prosthesis **and** application of iliac grafts to medullary cavity of femur.

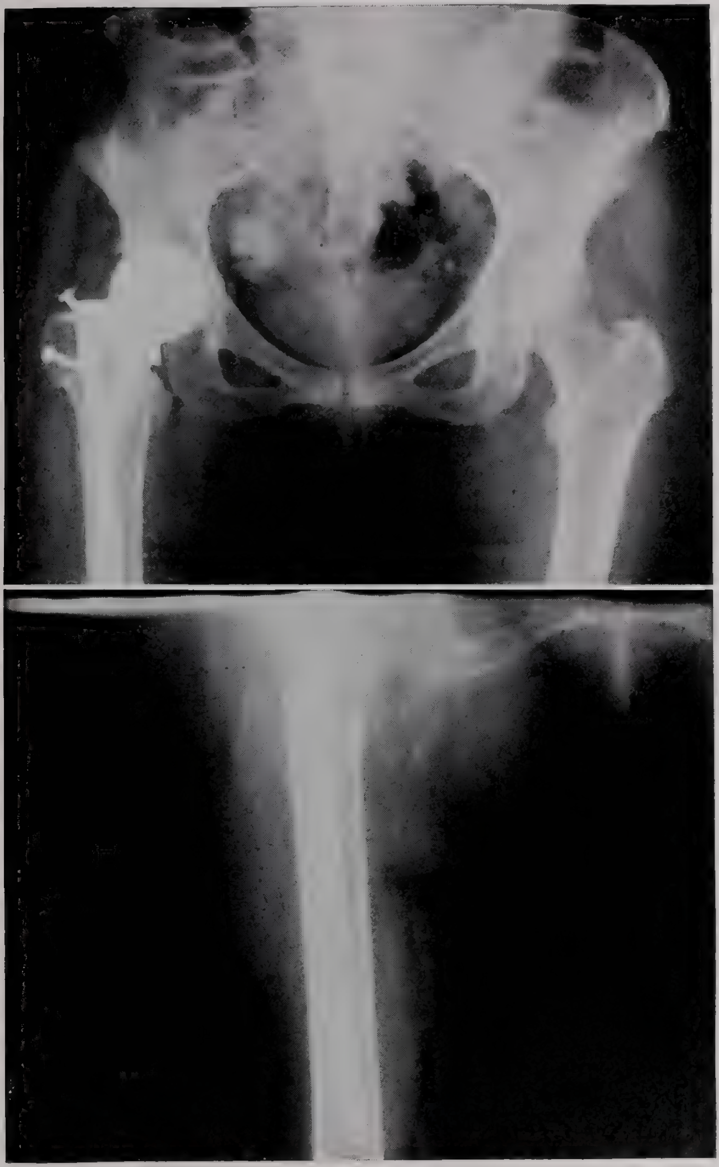

Fig. 18. (Case 5). Six months postoperatively.

I usually allow the average prosthesis patient to bear full weight after three months, but in this case I suggested that the patient stay on crutches for another two months. She was bearing weight on the right leg at time of follow-up.

In summary, these cases illustrate very well the statement that fracture about the hip is "an unsolved problem." Avascular necrosis of the femoral head, nonunion, resorption of the femoral neck, malunion of the fracture—all are complications that must be reckoned with. And often the measures taken to combat these complications carry with them another group of complications as the final two cases illustrate. Graft these problems onto a patient of advancing age and it is easy to understand why and how these problems become a real challenge to all doctors concerned with the treatment of such fractures.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

THE ADOLF GUNDERSEN MEDICAL FOUNDATION of La Crosse, Wisconsin, announces the establishment of a fully accredited three-year residency training program in Internal Medicine at Lutheran Hospital, La Crosse, Wisconsin. The hospital staff consists of a 65-man multiple specialty group with offices in a connecting modern clinic building. Eighteen fully qualified Internists serve as a nucleus of the teaching program. All staff men are full-time and salaried. This clinic-hospital complex serves as a referral center for a 100-mile radius. The hospital has a 375-bed facility. An intensive in-house training program is supported by weekly guest consultants. Stipend: $600 to $700 per month, plus housing and miscellaneous. Located in a progressive community with expanding university and private college. Population 50,000. Excellent school and recreation facilities. Applications being considered at all levels. Write: Edwin L. Overholt, M.D., Director, Medical Education and Research, Gundersen Clinic, Ltd., 1836 South Avenue, La Crosse, Wisconsin 54601.

GENERAL PRACTICE: INSTITUTIONAL: Desire a more regular life with regular hours, vacations, sick leave, time for attendance at meetings, etc? Consider working on a 60-bed medical service in a 350-bed psychiatric teaching hospital with a full-time Internist, several psychiatrists, part time surgeons and generalists at the Mental Health Institute, Cherokee, Iowa. Iowa licensure. Salary to $24,600 if eligible. Contact J. T. May, M.D., Superintendent.

INTERNIST—BROAD ELIGIBLE or Certified wanted to join two Internists, Radiologist, General Surgeon and EENT physician (all Mayo trained and Certified). Modern clinic building located in University city of Northeast Wisconsin having three fully equipped hospitals. For further information contact Administrator, Green Bay Clinic, 123 N. Military Ave., Green Bay, Wis. 54303.

WANTED: General Practitioner to join busy G. P. in ideal location. Partnership or salary with full hospital facilities. Contact M. J. Lindahl, M.D., Sherburn, Minnesota. Phone 507-764-4211 collect.

NEW EXPANDING OPPORTUNITIES for family physicians and physicians specializing in pediatrics, general surgery, internal medicine, urology, radiology, anaesthesiology; in medically-awakening community. Contemporary, automated, 105-bed, new hospital to be completed in the fall of 1970. Present hospital to be converted into long-term unit. Patient service area 50,000 people. Medical staff leading and supporting recruitment efforts. Excellent community location, forty miles equidistant to Milwaukee or Madison. Complete educational, cultural and recreational facilities. Possibility of new medical office building adjacent to new hospital. Immediate satisfaction in practice, income and family living. Special assistance if needed. Write or call Leo C. Bargielski, Administrator, Watertown Memorial Hospital, 1301 E. Main Street, Watertown, Wisconsin, 53094; telephone 414-261-4210 for more information.

OPPORTUNITY for career in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations. Give résumé. Write MINNESOTA MEDICINE—432, 375 Jackson, St. Paul 55101.

HALLOCK, MINNESOTA needs another general practitioner to help serve area population of 10,000. County seat town located in rich Red River Valley 65 miles north of Grand Forks or 65 miles south of Winnipeg. There is a facility in town, fully staffed and operating. Present solo general practitioner agreeable to employing, associating with, or cooperating with any practitioner interested. If interested, contact Roland Lartner, M.D. 843-4131.

WANTED: General Practitioner or Internist, to join four man group in St. Paul. Partnership possible in one year. Dr. V. L. Sommerdorf, 1239 Payne Avenue, St. Paul, Minnesota 55101.

EXCELLENT OPPORTUNITY for General Practitioner and General Surgeon to join 4-man general practice group. Services of Radiologist immediately available. Liberal time off and post graduate allowances. Salary open with opportunity for early partnership. College town, population of 10,000, 30 miles from Minneapolis-St. Paul. Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone number 425-5322.

If she asks what you think of babyScott

The next page will help you answer.

Introducing the babyScott diaper system. Designed with infants, mothers, and physicians in mind.

Two-part system offers clinical advantages as well as convenience and efficiency.

The diaper panty: it takes anatomy into consideration. The babyScott diaper panty is specifically designed to hold the babyScott disposable diaper securely, yet without constriction. The panty fits low in front to avoid pressure on the umbilicus. And high on the legs so it won't chafe, bind or interfere with mobility.

Four different sizes and multi-position snaps help assure good fit and comfort. "Safety" pins, which can always pose a threat, are completely unnecessary.

All portions of the panty that come in contact with the infant's skin are covered with soft, quick-drying cloth.

Essentially non-absorbent, the babyScott panty can be thoroughly and rapidly washed, rinsed and dried.

The disposable diaper: it takes sensitive skin into consideration. The disposable diaper, itself, is thick, fluffy and soft. Its layers of highly absorbent cellulose fluff are covered by a web-like liner, which is both permeable and relatively hydrophilic to help keep infants drier.

Doubly thick for extra absorption in front, the diaper fans out bucket-seat fashion in the back for wide coverage. The babyScott diaper thus provides excellent protection while minimizing bunching and consequent irritation. On those occasions when double diapers are used for extra protection comfort is still maintaine

With babyScott, each diaper comes fresh and clean out of the pack. It's used only once, then flushed away or otherwis disposed of.

No soap, detergent or bleach residues. No opportunity for cross contamination from the diaper.

A frequently changed infant is a healthier, happier infant.
And the babyScott diaper system is so easy to use, it will be used.

babyScott®
the pinless diaper

Dermatology

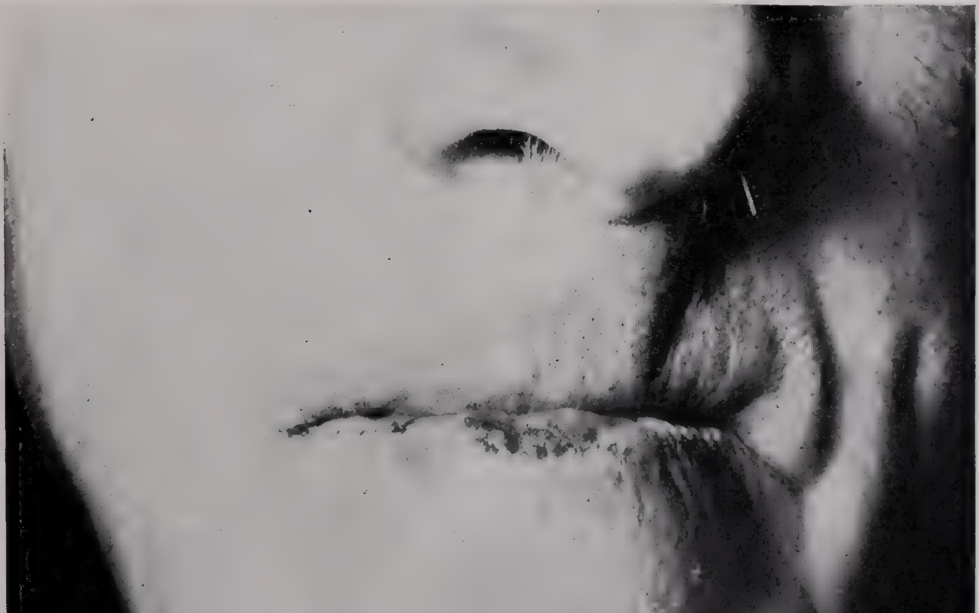
Leukoplakia

A Precancerous Dermatosis

THE TERM "precancerous" includes dermatoses in which the incidence of carcinoma is greater than should be expected when various factors such as age, exposure to sunlight, chronic irritation, and effects of previous treatments are considered. Leukoplakia, Bowen's disease, senile keratosis, cutaneous horn, and keratosis resulting from the ingestion of arsenic, exposure to tar, and iodizing radiation are precancerous. In at least 20% of these disorders squamous-cell carcinoma eventually develops. Seborrheic keratoses, certain nevi, tuberculous and stasic ulcers, lupus vulgaris, lupus erythematosus, epidermal cysts, and scars following burns are not precancerous. The incidence of carcinoma varies from only a fraction of 1% to about 5% in these disorders. Proper use of the term precancerous has a clinical and histologic meaning. It is valuable from the standpoint of prognosis and treatment.

Characteristics

Leukoplakia, derived from the Greek, means white plaque. Leukokeratosis implies that the lesion is thick and elevated. Leukoplakia occurs on the inner surfaces of the lips and cheeks, the dorsum and edges of the tongue, palate



Figure—Squamous-cell carcinoma superimposed on a leukoplakic area.

and gingivas. The disorder is not confined to the oral cavity; lesions may be present on the male and female external genitalia and the mucous membranes of the bladder, urethra, vagina, larynx, and esophagus.

The patches are usually white or grayish-white, superficial, and of various sizes and shapes. They may coalesce to form diffuse sheets distributed asymmetrically. An area becomes involved, peripheral extension follows, then other discrete plaques develop. The surface is glistening and opalescent, often reticulated, and the white pellicle is adherent to the underlying mucosa. Attempts to remove it forciby cause bleeding. Sometimes the lesions become elevated (leukokeratosis) and the surface irritated, inflamed, fissured, eroded, or ulcerated. These are "danger signals." The incidence of carcinomatous change in leukoplakia is difficult to determine: probably from 20 to 30%.

Clinical

Leukoplakia results from chronic irritation and trauma such as smoking, jagged or carious teeth, and poorly fitting dentures. Syphilis is unimportant. Leukoplakia appears most frequently during the fifth and sixth decades of life—occasionally during the second. The disease is much more common in men. Women who have the disorder are usually heavy smokers or have ill-fitting dentures.

Lichen Planus

Of all the maladies involving the oral cavity resembling leukoplakia, lichen planus* deserves first consideration. It may involve the buccal mucosa, the tongue, the lips, the hard palate, or the gingivas. Lesions are white, smooth papules with an inflammatory halo. They are annular, linear, or reticulated; they are rarely eroded. Lesions of lichen planus are not as thick as those of leukoplakia. The skin of the entire body should be examined carefully. Lichen planus frequently occurs on the flexor surfaces of the wrists and on the lower extremities.

Treatment

Treatment of leukoplakia consists of the removal of the local irritants, proper adjustment of dentures, cessation of smoking, and proper care of the teeth. Verrucous, fissured, or ulcerated lesions should be cauterized or desiccated. They are radioresistant. Surgical removal is occasionally indicated when the lesions are extensive.

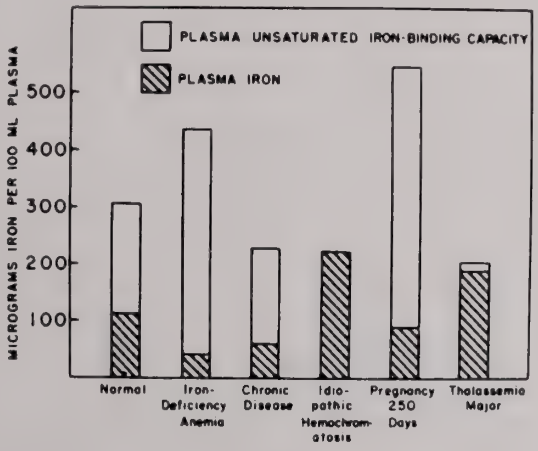
Rusty About Iron Metabolism?

IF YOU FEEL inadequate about your knowledge of iron metabolism, don't. Even authorities are uncertain what happens once iron molecules enter the body—how and where they are absorbed, how they are transferred from mucosal cells to the plasma, what precise functions they perform, where they are stored, or why, in certain diseases, the body becomes overloaded with or depleted of iron molecules.

But for clinical purposes, you usually don't need to chase down metabolic pathways. Given a good history, physical, and the values for total iron and iron-binding capacity, you can reach some sound conclusions about the nature of your patient's problem.

To do so, you have to judge the significance and the relation of the plasma iron and iron-binding capacity. Do the values indicate iron-deficiency anemia, pyridoxine-responsive anemia, chronic disease, thalassemia major, or hemochromatosis? This is not always an easy question to answer. But as a practical matter, you will find the following figure (from Moore[1]) useful in separating these conditions.



Figure

Of course, in using the figure, you should take into acount these normal values: 50-180 micrograms per 100 ml for total iron and 250-400 micrograms per 100 ml for iron-binding capacity. It would be foolhardy to suggest this approach will completely unravel the problem of interpreting serum iron values. It will not. For example, if your patient has a hypochromic anemia (and that, after all, is the usual reason you order the tests), you will want to distinguish these types of anemias.

TABLE*

Type of Anemia	Diagnostic Criteria			
	Wright's Stained Blood Film	Bone Marrow Hemosiderin	Serum Iron	Miscellaneous Features
Iron deficiency	Hypochromia Microcytosis Few target cells	Absent or greatly reduced	Low	Evidence of blood loss; rarely malabsorption or deficient intake. Responds to iron therapy.
Thalassemia syndromes	Hypochromia Microcytosis Many target cells Nucleated Rbc Basophilic stippling	Increased or normal	Elevated or normal	Often Mediterranean ancestry; hepatosplenomegaly. Elevated fetal or A_2 Hgb; elevated bilirubin and other evidence of hemolysis.
Pyridoxine-responsive anemia	Hypochromia Microcytosis	Increased	Elevated	Rare; often abnormal tryptophane-loading test; responds to parenteral pyridoxine.
Hereditary hypochromic anemias	Hypochromia Microcytosis	Increased	Elevated	Type described by Cooley, Falls and Rundles occurs in males only; sideroachrestic type (Heilmeyer's) occurs mainly in males with sideroblasts in the bone marrow. Neither type responds to iron therapy.

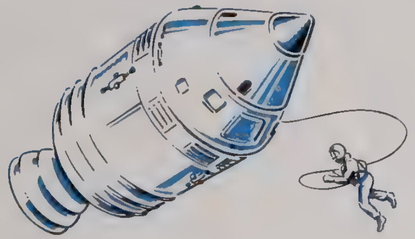
Changes in the Spectrum of Disease

Variations in the spectrum of disease which doctors are called upon to treat have always been a reality in medicine, although in the recent past, the changes in the patterns of illness have been far more rapid and extensive than anything ever seen before. Recently, a young graduate of our medical school left practice in a small Minnesota town to become part of a missionary medical group in a medically backward country in Southeast Asia. In leaving, he announced that he expected to see "more real pathology" in two weeks in Asia than he would see in his Minnesota practice in a year. From the balance of his remarks, it seemed evident that he was going off to find a "real medical practice," suggesting that practice as it now exists in Minnesota has so changed from the established pattern as to no longer be the genuine article. The changing pattern of illness from the dramatic epidemic scourges of yesteryear to the heavy predominance of the deterioration of age, malignancy, etc., has obviously affected medical practice, although not always necessarily in obvious ways.*

---

*Magraw, Richard M., M.D.: Ferment in Medicine, 1966.



Man in space, now fait accompli, re-emphasizes the importance of Uro-Phosphate therapy. Research into the effect of space travel on the astronaut reveals that weightlessness causes loss of bone calcium. As the bones are required to bear less and less of the weight of the body they lose calcium, increasing the calcium content of the urine. When physical activity is reduced, the acidity of the urine should be adjusted to keep increased calcium in solution . . . . a prophylaxis to prevent kidney or bladder calculi.

Uro-Phosphate®

NOW A SUGAR-COATED TABLET

Each tablet contains: METHENAMINE, *300 mg.;* SODIUM ACID PHOSPHATE, *500 mg.*

Uro-Phosphate gives comfort and protection when inactivity causes discomfort in the urinary function. It keeps calcium in solution, preventing calculi; it maintains clear, acid, sterile urine; it encourages complete voiding and lessens frequency when residual urine is present.

Dosage:

For protection of the inactive patient 1 or 2 tablets every 4 to 6 hours is usually sufficient to keep the urine clear, acid and sterile.

2 tablets on retiring will keep residual urine acid and sterile, contributing to comfort and rest.

A clinical supply will be sent to physicians and hospitals on request.

Uro-Phosphate contains sodium acid phosphate, a natural urinary acidifier. This component is fortified with methenamine which is inert until it reaches the acid urinary bladder. In this environment it releases a mild antiseptic keeping the urine sterile.

Uro-Phosphate is safe for continuous use. There are no contra-indications other than acidosis. It can be given in sufficient amount to keep the urine clear, acid and sterile. A heavy sugar coating protects its potency.

Tetracycline HCl

250 mg. and 100 mg. capsules

Contraindications: Hypersensitivity to tetracyclines. *Warning:* In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs. *Precautions:* Nonsusceptible organisms may overgrow; treat superinfection appropriately. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Side Effects: Gastrointestinal—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity reactions*—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

"coughing
is not a harmless
privilege"—Current Therapy 1967, ed. by Conn, H. F., P. 88—

if cough
serves no useful
purpose

Rx **Tussionex**®
(Resin complexes of Hydrocodone and Phenyltoloxamine)

. . . it works
(usually
for 10 to 12
hours*)

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic—oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.

***DOSAGE**: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

Grand Rounds

Penicillin Hypersensitivity*

MARY G. MAHERAS, M.D.
Minneapolis, Minnesota

An Immunological Approach

PENICILLIN IS considered non-toxic in man in spite of irritative effects; but, on the other hand, it is regarded as the most common cause of drug allergy. About 15% of the population is estimated to be sensitized.[1] Estimates of incidence vary from 1% to 10% of persons treated with penicillin; the lower figure may be more accurate in reference to an ambulatory population, while the higher figure may be more applicable to a hospital population.[2] In a recent study at Johns Hopkins University Hospital, 7.8% of hospitalized medical patients treated with penicillin had penicillin reactions.[3]

Diagnosis

The diagnosis of penicillin hypersensitivity may be very difficult to establish and is dependent on satisfying criteria of history, clinical findings, and proof of specific hypersensitivity.[4]

The History

Factors of historical significance include: atopy; family history of penicillin sensitivity; history of reaction to other drugs; frequency of penicillin exposure; route of penicillin administration; and type of penicillin preparation. Atopy, a positive family history, and other drug sensitivities are all associated with an increased incidence of penicillin hypersensitivity.[3,4]

The Preparation

There is also an increased rate of reaction with increasing frequency of exposure; the constant exposure to penicillin-contaminated products in the daily environment, such as milk products, may assume clinical significance.

---

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, November 5, 1968.

Parenteral penicillin preparations are associated with higher incidences of sensitivity than oral or topical preparations.[1,4] Procaine preparations have an incidence of reaction of about 5%; aqueous preparations, about 2.5%; and oral and benzathine preparations, approximately 0.3%.[1]

Clinical Manifestations

The clinical manifestations of penicillin hypersensitivity are entirely nonspecific. Studies are cited in which maculopapular rashes, arthralgias, pruritus, and fevers occurred with equal frequency when healthy subjects were treated with either benzathine penicillin or saline. This was not true, however, in instances of serum sickness, urticaria, and local reactions; these clinical findings occurred more frequently in subjects treated with the benzathine penicillin.[3] Cutaneous reactions range from erythema and urticaria to syndromes of the Henoch-Schoenlein variety and lupus erythematosus. These reactions are usually only one manifestation of a generalized hypersensitivity state.[4]

Classification

The following classification of Levine will be used throughout the remainder of this paper when referring to the manifestations of penicillin sensitivity:[5]

Immediate Reaction (developing within two to 20 minutes)

1. Hypotension-shock
2. Diffuse urticaria
3. Wheezing
4. Rhinitis
5. Laryngeal edema

Accelerated Reaction (developing within two to 48 hours after the initiation of treatment)

1. Urticaria
2. Occasionally laryngeal edema

Late Reactions (developing after three days of treatment)

1. Skin rashes
2. Drug fever
3. Hemolytic anemia
4. Thrombocytopenia
5. Proteinuria with or without azotemia
6. Urticaria
7. Recurrent urticaria and arthralgia

Immunological Basis of Hypersensitivity:

Antigenicity of Benzylpenicillin:

$$\text{Antigen—Antibody} \longrightarrow \text{Allergic Reaction}$$

The first requirement for the induction of an immune response is a complete antigen. Studies have shown that low molecular weight compounds, such as penicillin, must react irreversibly with proteins to sensitize or elicit an allergic reaction. Penicillin itself has not been shown to combine irreversibly with protein; therefore it is postulated that either a contaminant or metabolic product must be the "pro-antigen," i.e., hapten, the substance that reacts irreversibly with tissue protein to form a complete antigen.[5,6] The irreversible binding of the hapten to the tissue protein is a chemical covalent bond. To form these bonds a portion of the drug molecule must be in a reactive form; the reaction occurs with amino acid residues such as lysine, tyrosine, or histidine, capable of forming a charge on their side chains.[6,7]

Levine and Ovary investigated the in-vitro reactions of benzylpenicillenic acid with various proteins (human gamma globulin, human serum albumin, gelatin, polylysine,) and found that benzylpenicillenic acid reacted primarily with lysine-E-amino groups to form a diastereomeric mixture of benzylpenicilloyl-lysine groups. A smaller reactivity occurred with disulfide linkages to form benzylpenicillenic acid cysteine-mixed disulfide, and D-penicillamine cysteine-mixed disulfide. By challenging rabbits sensitized with penicillin G they observed reactions specific for the benzylpenicilloyl-lysine groups. No antibodies to the the benzylpenicillenic acid-disulfide or D-penicillamine groups were detected. Using additional methods of precipitation, guinea-pig passive cutaneous anaphylaxis, and quantitative inhibition with E-amino caproic acid they further confirmed the specificity for the diastereomeric benzylpenicilloyl groups. They thus concluded that benzylpenicilloyl-lysine groups are major antigenic determinants for penicillin G hypersensitivity, and that the penicillin system behaves similarly to protein and protein-conjugated systems with precipitating antibodies, skin-sensitizing antibodies, and hapten inhibition.

The failure of the mixed disulfide conjugates to form detectable antibodies was attributed to insufficient formation of conjugates containing these groups in vivo, and therefore insufficient antibody formation. Serum albumin and globulin contain many lysine-E-amino groups, but relatively very few disulfide linkages; conversely, epidermal proteins contain relatively large numbers of cysteine disulfide linkages.

Parker et al. subsequently investigated the benzylpenicilloyl and benzylpenicillenate groups as specific determinants of allergic benzylpenicillin reactions in humans. They employed the method of eliciting wheal and erythema responses, and univalent hapten inhibition. They concluded that multifunctional derivatives of penicillenic acid are effective elicitors of wheal and erythema responses in humans allergic to penicillin. Significant derivatives are penicilloyl, penicillenate, and penamaldate-penilloaldehydes. The former is the major determinant, and the latter two minor determinants.[9] Some 95% of penicillin that is bound is in the form of the benzylpenicilloyl group.[5]

Parker's study is summarized in the following table:[9]

TABLE I

History	BPO-Lys skin test		Penicillenate-S-HSA skin test			
	+	—	+BPO test		—BPO test	
			+	—	+	—
Previous allergic reaction	45	14	12	10	0	6
No previous allergic reaction	44	1147	12	12	0	12

Out of the total 1250 subjects tested only two had systemic reactions to the skin test; both of these tests included the penicillenate-S-HSA. The use of BPO polylysine derivatives themselves has not been found to elicit detectable antibody formation.

Antibody Formation

The immunoglobulins, i.e., antibody-carrying globulins, are the gamma and beta globulins. These globulins are composed of light and heavy polypeptide chains and are divided into four major classes according to the heavy (H) chains:

IgG
IgM
IgA
IgD

As shown from animal studies, different antibody classes mediate different allergic reactions. For example, there is some data to indicate that immunoglobulin G and immunoglobulin M antibodies fix complement and therefore mediate serum sickness and hemolytic reactions. Investigators have not yet been able to classify skin-sensitizing antibodies; functionally, however, we do know that these antibodies are specific for the immunizing antigenic determinant.

Only semi-quantitative methods are available currently for antibody assays. The wheal and flare reaction is used for the detection of skin-sensitizing antibodies (SSA), i.e., antibodies that are fixed to the skin. The benzylpenicilloyl skin-sensitizing antibodies are detected with the low molecular weight benzylpenicilloylpolylysine conjugates. The reaction is elicited by bridging a small number of "tissue-fixed" skin-sensitizing antibody molecules, which results in histamine release. The skin-sensitizing antibody of the minor antigenic determinants is detected by testing with a minor determinant mixture of benzylpenicillin, benzylpenicilloate, and benzylpenilloate; these determinants probably react with protein in the skin to form the complete antigen that can react in the wheal and flare.

Benzylpenicilloyl specific immunoglobulin G and immunoglobulin M antibodies can be determined by hemagglutination methods employing OS human red blood cells that have coupled to benzylpenicilloyl groups. To date no method for assaying immunoglobulin G or immunoglobulin M antibodies specific for the minor determinants has been developed.[5]

Inferences from Table 2 and other data can be applied to the classification of allergic penicillin reactions presented previously.

Immediate Reactions

These reactions are nearly 100% associated with minor determinant skin-sensitizing antibodies. Prospective studies have shown that persons with positive wheal and flare reactions to the minor determinants have immediate reactions when challenged with penicillin. Persons with immunoglobulin G or immunoglobulin M antibodies only have failed to develop the immediate reaction.

Accelerated Reactions

The accelerated hypersensitivity reactions have been associated with skin-sensitizing antibodies and immunoglobulin G antibodies of penicilloyl specificity. It is postulated that they are mediated by skin-sensitizing antibodies and that the immunoglobulin G antibodies serve as "blocking" antibodies. A rising immunoglobulin G titer has been associated with the disappearance of urticarial reactions in spite of continued treatment with penicillin. Prospectively, patients developed their urticaria at low titers of immunoglobulin G, and it disappeared with the anamnestic response and rising titers. A negative set of skin tests can rule out the possibility of immediate or accelerated reactions.

Late Reactions

The late urticarial reactors also seem to be mediated by benzylpenicilloyl specific skin-sensitizing antibodies. Whereas the accelerated urticarial reactors already have a titer of antibodies when they are challenged, the late urticarial reactors develop their titer during the course of treatment; i.e., the course of treatment provides both the sensitizing and the challenging dose in the late urticarial reactors.

Of interest was the near 100% association of minor determinant skin-sensitizing antibodies with the late reaction of current urticaria and arthralgia. In contrast to the immediate reactions, which are apparently more sensitive to benzylpenicilloate, these reactors are more sensitive to benzylpenicillin.

Maculopapular and erythematous reactions were associated with high titers of immunoglobulin M antibodies; it is postulated that they may be mediated by double antigen-antibody reactions. An immunoglobulin titer of greater than 1:1000 adds support to a diagnosis of maculopapular penicillin sensitivity.

Some 5-10% of patients on long-term parenteral penicillin therapy may develop a Coombs' positive hemolytic anemia. The hemolytic reaction occurs when benzylpenicilloyl specific antibodies react with erythrocyte-benzylpenicilloyl conjugates. A high titer of immunoglobulin G antibodies may increase the incidence of hemolysis.[5]

TABLE 2

MECHANISMS OF ALLERGIC REACTIONS:

Antibody Patterns in Nonreactors to Benzylpenicillin[6]

	Percentage of patients with antibody pattern		
Antibody pattern	117 with no penicillin therapy	103 with recent moderate dose therapy	12 with recent high dose therapy
None detected	3	0	0
IgM only	77	61	92
IgG and IgM	17	30	8
SSA to BPO plus IgG and IgM	3	8	0
SSA to BPO plus SSA to minor determinants plus IgG and IgM	0	1	0

Nearly 100% of the non-reactors demonstrated the presence of antibodies. This data demonstrates that the presence of antibodies does not necessarily mean sensitivity. One must consider the type and quantity of antibody as well as individual differences.

Antibody Patterns in Allergic Reactors to Benzylpenicillin[6]

	Percentage of patients with antibody pattern:				
Antibody Pattern:	12 immediate reactions	10 accelerated reactions	11 late urticarial reactions	16 recurrent urticaria & arthralgia	15 maculopapular & erythema reactions
IgM only	0	0	0	0	58
IgM (high titers)	0	0	0	0	32
SSA to BPO plus IgG and IgM	0	60	91	0	5
Minor determinant SSA plus IgM	42	0	0	56	0
Minor determinant SSA plus IgM & IgG	16	0	0	25	0
BPO-SSA, minor determinant SSA, IgG, IgM	42	40	9	19	5

Clinical Detection of the Penicillin Reactor

A primary concern in clinical medicine is the detection of the potential anaphylactic reactor whenever the slightest possible history of penicillin allergy is encountered. Investigators have demonstrated the predictive value of skin testing and the relative safety of treating with penicillin in the presence of negative skin tests.[10,11] As pointed out by Levine, however, it is necessary to include the minor determinants in the skin-testing procedures; currently the necessary antigenic substances are not available for widespread clinical use. Clinicians are thus still required to use second choice antibiotics in situations where penicillin is regarded as the drug of choice.

Hemagglutinating techniques are available, but at this time they are highly impractical on a large scale and of very questionable validity as to predictive values.[12]

An in-vitro procedure based on the microscopic degranulation of basophils during the antigen-antibody reaction is also described. The degranulation of the basophils is representative of histamine release. A positive test means only that a measurable titer of antibodies was present at the time the test was carried out.[13,14] This procedure is also impractical, and involves considerable subjective human interpretation.

A more recent test based on the fluorometric assay of histamine released from rabbit basophils is under investigation. It is dependent on histamine release from rabbit basophils when the cells are mixed with sensitized sera and penicillin.[15] This test is more scientifically and technically controlled than the previously described degranulation test, but no clinical studies are available in the literature.

In summary, an outline is provided for an immunological understanding of the clinical entity of penicillin allergy. Its clinical application is limited because of the impracticality of large-scale efforts to determine potential reactors, the unavailability of laboratory techniques in the average hospital, and the availability of increasing numbers of effective substitute antibiotics.

It is left for the clinician to take such prophylactic measures as a thorough history, the use of penicillin only when indicated, the use of the minimal dosage necessary for the therapy, the use of the safest route possible, the use of the safest preparation indicated, and preparation for reactions.[4] It is hoped that advantage will be taken of whatever skin-testing procedures or laboratory techniques are available.

Clinical Case Report

The patient was an 18-year-old student nurse who was hospitalized at age 16 for a period of two weeks because of rheumatic fever. She was told by her physician that she had a heart murmur initially which disappeared during hospitalization. She was discharged on prophylactic penicillin and convalesced for a period of four months.

Ten days prior to the current admission she developed a sore throat and swollen cervical nodes. The initial throat culture taken in the Emergency Room was negative; but as repeat culture was positive for beta hemolytic streptococcus, she received intramuscular penicillin (bicillin). The day following the injection a rash resembling "insect bites" developed on her lower extremities. She was again seen in the Emergency Room and started on a course of Prostaphlin for suspected folliculitis. The following day she noted the onset of pain in the left ankle and left elbow and was admitted to the hospital.

Physical examination on admission was positive for small posterior cervical nodes, a low-grade systolic murmur in the pulmonic area, and a tender left ankle and left elbow; a macular rash was present on the trunk.

During her hospital course she remained afebrile and was free of the rash and arthralgia within 48 hours. Laboratory data revealed a persistent eosinophilia of 8-11% and an ASO titer that rose from 250 to 500. Her final diagnosis was that of penicillin allergy and she was discharged on prophylactic sulfadiazine.

The Progress Notes of Hypocrates

Meton* was seized with fever; there was a painful weight in the loins. Next day, after drinking water pretty copiously, had proper evacuations from the bowels. On the third, heaviness of the head, stools thin, bilious, and reddish. On the fourth, all the symptoms exacerbated; had twice a scanty trickling of blood from the right nostril; passed an uncomfortable night; alvine discharges like those on the third day; urine darkish, had a darkish cloud floating in it, of a scattered form, which did not subside. On the fifth, a copious hemorrhage of pure blood from the left nostril; he sweated, and had a crisis. After the fever restless, and had some delirium; urine thin, and darkish; had an affusion of warm water on the head; slept and recovered his senses. In this case there was no relapse, but there were frequent hemorrhages after the crisis.†

Famous Men and Their Poor Health

"Good God! What a man! What a genius! Such knowledge and such a mind!" This was Gustave Flaubert's tribute to Baruch Spinoza whose all too short life spanned only the years between 1632 and 1677.

In Hebrew Baruch means blessed. And young Spinoza was blessed—mentally, morally, spiritually—but not physically. As a tubercular child refugee from the Spanish Inquisition he accompanied his family to Holland where he grew up in Amsterdam Jewry but spent most of his adult life in the little Dutch town of Voorburg. There we see him living alone in a small, dusty room industriously grinding and polishing lenses for a meager subsistence.

Why the vocation of lens-grinder and polisher? The good Jew of Spinoza's era conscientiously honored and observed the traditional admonition that to be whole a man should learn and engage in a solid and worthy handicraft. "He who earns his living by toil is greater than he who fears God," said the Talmud. And it so happened that scientifically-oriented Baruch was attracted to lens-craft for three reasons in particular: from reading Descartes he had become interested in the field of optics; Huygens' telescope had recently discovered Saturn's largest satellite; and Leeuwenhoek was just then engaged in refining and perfecting the microscope that would later furnish a detailed view of blood corpuscles. Then too, while grinding and polishing, Baruch could think: formulate his majestic philosophical concepts and plan his literary work.

Considering his inexorably advancing phthisis, however, he could scarcely have chosen a more deleterious occupation. Dust filled his closed, cramped room and was inhaled into his diseased lungs. But, perfectionist that he was, he continued with each lens until it reached the acme of perfection. In Robert Smith's book on optics he says that for mere adequacy a single lens requires as many as 3,000 strokes on each side. And Baruch used only a treadle lathe!

He didn't go out for fresh air. Milk porridge and groats comprised his scanty diet. "Nature is satisfied with very little, and if nature is satisfied then so am I," he said.

So, emaciated, flushed, coughing, sweating, spitting, often too weak to stand without support, young Spinoza ineluctably wasted away. If he wondered why, he never asked or complained. But as the mortal body faded to a mere shadow, the inner spiritual light glowed the brighter in its transcendence of the corporeal and the temporal. Transfiguration, we call the phenomenon!

One Sunday morning Baruch had his usual cheerful chat with his landlady's family, agreeing to continue the conversation after their return from church. But the visit was never resumed. Baruch went to bed, his doctor sitting at his side, and quietly died. That is, his body did. But not his spirit. For it, resurrection followed in the posthumous publication of his philosophical and literary masterpiece (15 years in the writing and prudently withheld during his lifetime): his "Ethics," whereby he bequeathed to the ages his magnificent philosophical tenets: that mind and matter are not a dichotomy but twin attributes of Reality; that man is not a special creation but rather a single aspect of the vast immanence of Nature (God) as revealed in the total cosmos.*

*With quotations from and acknowledgments to Rudolf Kayser: Spinoza, 1946.

One of these disposables comes prefilled.
Its unit dose – in nonreactive glass
cartridge – is premeasured.
The cartridge is clearly labeled:
drug name, strength, control number.
Even expiration date where appropriate.

You're more confident that the patient gets…

. . . just what the doctor ordered with the Tubex Closed Injection System.

Injections with the Tubex system are as easy as 1, 2, 3,

1. Select—from an extensive variety of prefilled Tubex sterile cartridge-needle units.* No multi-dose vials to bother with; no unlabeled syringes to cause confusion.

2. Inject—with a minimum of pain. Thanks to the single-use, stainless-steel needle that's both ultra-sharpened and siliconized. Aspirate simply and conveniently.

3. Throw away—empty cartridge-needle unit. Never used again, it can't transmit infection. And there's no clean-up job.

*For injectables not yet in the ever-expanding prefilled Tubex line, empty sterile cartridge-needle units are available.

Childhood Rickets:

Revival of an Ancient Menace

When has any physician last seen a child with rickets? Readers of the JAMA[1] may have been surprised recently by the report of an outbreak in Canada of childhood rickets of near epidemic proportions. Dr. Charles R. Scriver has stated that each year about 50 children with rickets have been admitted to Montreal Children's Hospital. In Quebec, the disease rate is 10 times higher than in the United States. A recent survey of 226 institutions in the United States showed that the incidence of rickets was only one child per 2,791 admissions.

What then accounts for this difference? In Canada, there is no compulsory legislation to force the provinces to comply with the 1965 recommendations of the Canadian Federal Government that milk should contain 300 to 400 international units of vitamin D per quart. Dr. Gelinas, the Quebec Deputy Minister of Health, is presently working with various medical, federal, and provincial groups in an effort to formulate and pass mandatory legislation.

A Brief History of the Clinical Investigation of Rickets

Findlay[2] stated that the first reference to rickets can be attributed to Soranus of Ephesus (98-138 A.D.), who claimed that the disease occurred in children because of the neglect of the Roman mothers and the cold and dampness of the domiciles. In 1650 Glisson[3] presented the first definitive clinical and pathomorphologic work of any scientific significance. Previously, in 1645, Whistler[4] had discussed rickets in his work "De Morbo Puerili Anglorum." No doubt the title was responsible for the appellation "English disease" being given to rickets by German and other European writers. The term persisted even until the latter part of the 19th century, as witnessed in Kisel's[5] report in 1897 of English disease in the children of Moscow.

In 1895 Snow[6] conducted an extensive investigation of environmental factors as a cause of rickets in the children of Italian immigrants living in Buffalo, N. Y. Snow noted that the incidence of childhood rickets in Italy was low, whereas the incidence in the immigrant children was very high. He concluded that lack of housing, inadequate sunshine, improper food, and frequent childhood maladies combined to produce a high incidence of childhood rickets. Such thinking persisted in American pediatrics for an additional 25 years.

The Recognition of the Efficacy of Cod Liver Oil

According to Park,[7] Trousseau and his student, Bretonneau, two French physicians of the 18th century, advocated cod liver oil as a specific remedy in the therapy of rickets.

In 1878, Cheadle[8] presented the case histories of three children who had scurvy and rickets, but cod liver oil was given to only one of the three, affirming that Cheadle had neither the knowledge nor the conviction as to the specificity of cod liver oil in the therapy of rickets.

In 1909 Schabad,[9] a Russian pediatrician, demonstrated in studies of metabolic balance in children with rickets that administration of cod liver oil and phosphorus was associated with increased retention of calcium and phosphorus when the group was compared to rachitic children who were untreated. In England in 1919 Mellanby[10] isolated an organic fat-soluble substance that effectively prevented experimental rickets in puppies. In 1924 Windaus[11] isolated crystalline vitamin D by irradiation of ergosterol.

In the United States, Shipley and associates[12] in 1921 demonstrated proof of the curative action of cod liver oil by the deposition of lime salts in the cartilage of rachitic rats.

Even at the present time, the essential action of vitamin D remains unknown, though the transport of calcium and phosphate ions is somehow influenced thereby, and vitamin D is important in the regulation of the concentration of these ions at three loci—intestines, kidney, and bone.

In the 1950s, the possibility that the addition of vitamin D to milk could be excessive was proved. This excess resulted in many instances of hypercalcemia in Great Britain as well as in the United States. Also noted was the association of supravalvular aortic stenosis in these children with hypercalcemia. Subsequently, such lesions have been produced in puppies through excessive dosage of vitamin D to pregnant bitches.

Geographic Distribution of Rickets

Rickets is a disease that predominates in the temperate zones. It had been recognized that rickets was more prevalent in industrial areas because of poor housing and diminished sunlight exposure. By contrast, the disease was almost nonexistent in coastal areas of the same temperate zones because of the prevalence of fish in the diet. Herring and mackerel, common foods in these coastal areas, have a high content of vitamin D, namely 1,500 units of vitamin D per 100 gm. Eskimos have a diet consisting principally of fish and animal oils, a fact that has prevented rickets in their children.

Rickets Today

Three stages in the development of childhood rickets are recognized. Hypocalcemia and tetany in infants represent the first stage. The second stage, occurring at five to seven months of age, is manifested by normal levels of serum calcium but low levels of serum phosphorus and by hyperaminoaciduria. In the third stage, clinical rickets is evident radiologically as well as clinically.

Recognition of low serum calcium and phosphorus values and the use of a urine screening test for hyperaminoaciduria are important in children suspected of having latent or incipient rickets. Basically, rickets is a disease of poverty, and the opportunities provided by the Head Start Program may serve as an important means of checking on the nutrition of young children from ghetto and underprivileged areas. While we have been busy with contemporary problems of communicable diseases and vaccines, childhood rickets, an age-old scourge of the health of children, has returned.

Exorcism*

"I exorcise thee, Peter, or thee, Barbara, being weak but reborn in Holy Baptism, by the living God, by the true God, by God Who redeemed thee with His precious Blood, that thou mayest be exorcised, that all the illusions and wickedness of the devil's deceits may depart and flee from thee together with every unclean spirit, adjured by Him Who will come to judge both the quick and the dead, and who will purge the earth with fire. Amen."

IT'S THE LAW

No Negligence in Treatment of Perirectal Wound

The patient received a perirectal wound while water skiing. His physician observed the wound and cleaned it. He did not suture it. While the patient was still in the physician's office, the wound began bleeding. The physician once again examined the wound and sutured it. He placed the patient in the hospital for observation. The following day the patient was released from the hospital and returned to his home in a neighboring city.

Subsequently, he required hospitalization and a laparotomy for removal of a contaminated jagged wood splinter within the peritoneal cavity which had caused peritonitis, infection and putrefaction. Malpractice suit was brought against the initial examining physician. The court held, however, that the initial examining physician was not in error in his treatment of the wound.

THE BREAKUP of a business partnership, the crack-up of a marriage, the shake-up of being fired or reduced to bankruptcy…after any significant loss or severe blow to self-esteem, *both* anxiety and depression almost always follow.

FOR MODERATE TO SEVERE ANXIETY WITH COEXISTING DEPRESSION

TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

Containing perphenazine and amitriptyline HCl

For prescribing information, including indications, contraindications, warnings, precautions, and side effects, please see following page.

FOR MODERATE TO SEVERE ANXIETY WITH COEXISTING DEPRESSION

TRIAVIL®

TRANQUILIZER-ANTIDEPRESSANT

Containing perphenazine and amitriptyline HCl

TRIAVIL® 2-25: Each tablet contains 2 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.

TRIAVIL® 4-25: Each tablet contains 4 mg. of perphenazine and 25 mg. of amitriptyline hydrochloride.

TRIAVIL® 2-10: Each tablet contains 2 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

TRIAVIL® 4-10: Each tablet contains 4 mg. of perphenazine and 10 mg. of amitriptyline hydrochloride.

INDICATIONS: Patients with moderate to severe anxiety and/or agitation and depressed mood; patients with depression in whom anxiety and/or agitation are severe; patients with depression and anxiety in association with chronic physical disease; schizophrenics with associated depressive symptoms.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; urinary retention; pregnancy; glaucoma. Do not give in combination with MAOI drugs because of possible potentiation that may even cause death. Allow at least 2 weeks between therapies. In such patients therapy with TRIAVIL should be initiated cautiously, with gradual increase in the dosage required to obtain a satisfactory response.

WARNINGS: Patients should be warned against driving a car or operating machinery or apparatus requiring alert attention, and that response to alcohol may be potentiated.

PRECAUTIONS: Suicide is always a possibility in mental depression and may remain until significant remission occurs. Supervise patients closely in case they may require hospitalization or concomitant electroshock therapy. Untoward reactions have been reported after the combined use of antidepressant agents having various modes of activity. Accordingly, consider possibility of potentiation in combined use of antidepressants. Not recommended for use in children. Mania or hypomania may be precipitated in manic-depressives (perphenazine in TRIAVIL seems to reduce likelihood of this effect). If hypotension develops, epinephrine should not be employed,as its action is blocked and partially reversed by perphenazine. Caution patients about errors of judgment due to change in mood.

SIDE EFFECTS: Similar to those reported with either constituent alone.

Perphenazine: Should not be used indiscriminately. Use caution in patients with history of convulsive disorders or severe reactions to other phenothiazines. Likelihood of untoward actions greater with high doses. Closely supervise with any dosage. Side effects may be any of those reported with phenothiazine drugs: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); extrapyramidal symptoms (opisthotonos, oculogyric crisis, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; severe acute hypotension (of particular concern in patients with mitral insufficiency or pheochromocytoma); skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; endocrine disturbances (lactation, galactorrhea, disturbances of menstrual cycle); grand mal convulsions; cerebral edema; altered cerebrospinal fluid proteins; polyphagia; paradoxical excitement; photophobia; skin pigmentation; failure of ejaculation; EKG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in the pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia; significant unexplained rise in body temperature may suggest intolerance to perphenazine, in which case discontinue. Antiemetic effect may obscure signs of toxicity due to overdosage of other drugs or make diagnosis of other disorders such as brain tumors or intestinal obstruction difficult. May potentiate central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol), atropine, heat, and phosphorous insecticides.

Amitriptyline: Careful observation of all patients recommended. Side effects include drowsiness (may occur within the first few days of therapy); dizziness; nausea; excitement; hypotension; fainting; fine tremor; jitteriness; weakness; headache; heartburn; anorexia; increased perspiration; incoordination; allergic-type reactions manifested by skin rash, swelling of face and tongue, itching; numbness and tingling of limbs, including peripheral neuropathy; activation of latent schizophrenia (however, the perphenazine content may prevent this reaction in some cases); epileptiform seizures in chronic schizophrenics; temporary confusion, disturbed concentration, or transient visual hallucinations on high doses; evidence of anticholinergic activity, such as tachycardia, dryness of mouth, blurring of vision, urinary retention, constipation, paralytic ileus; agranulocytosis; jaundice. The antidepressant activity may be evident within 3 or 4 days or may take as long as 30 days to develop adequately, and lack of response sometimes occurs. Response to medication will vary according to severity as well as type of depression present. Elderly patients and adolescents can often be managed on lower dosage levels.

Physician's Workshop

The Velcro Rale

A PHYSICAL SIGN with high specificity of meaning is of inestimable value to the clinician. Proper elicitation or identification of such a sign is, however, often fraught with difficulty. Among the most difficult signs to identify correctly and, moreover, to teach to students are those generated by sound. Sounds related to auscultation of the lungs, by and large, bear relatively nonspecific meaning to such an extent that some chest physicians consider the stethoscope to be an anachronistic tool. This view notwithstanding, it is my opinion that sounds generated by the lung can be extremely helpful to less skeptical clinicians.

It has long been recognized that "dry" or "crackling" rales have been associated with pulmonary fibrosis. These rales have been compared to the crackling of cellophane. In my experience these descriptions are not satisfactory in terms of teaching because of their vagueness and lack of reproducibility for demonstration. I have found that the sound generated by tearing apart mated strips of Velcro adhesive, often used as fasteners on blood pressure cuffs, represents a striking reproduction of the rales of pulmonary fibrosis. In addition, the sound is easy to demonstrate repetitively to students and rapidly and effectively fixes it in their memories. The sound seems specific for pulmonary fibrosis. I have not heard it in other diffuse pulmonary conditions such as sarcoidosis, lymphogenous metastatic carcinoma, or pulmonary congestion. I have found the presence of digital clubbing and so-called Velcro rales almost diagnostic of pulmonary fibrosis.

The next time a clinician removes his Velcro-equipped blood pressure cuff from a patient's arm, he is urged to take note of the sound.

Automation and Medicine

Most physicians tend to think of computers in medicine as having a "far out into the wild blue yonder" aspect. To some this is stimulating; however, many persons tend to resent things which are hard to understand and the normal reaction is one of conservatism . . . As understanding and experience improve, physicians can move from conservatism to active use of these splendid instruments in the practice of medicine.*

Butisol SODIUM®

(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. BUTISOL SODIUM (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

McNEIL

McNeil Laboratories, Inc., Fort Washington, Pa.

No place for beginners

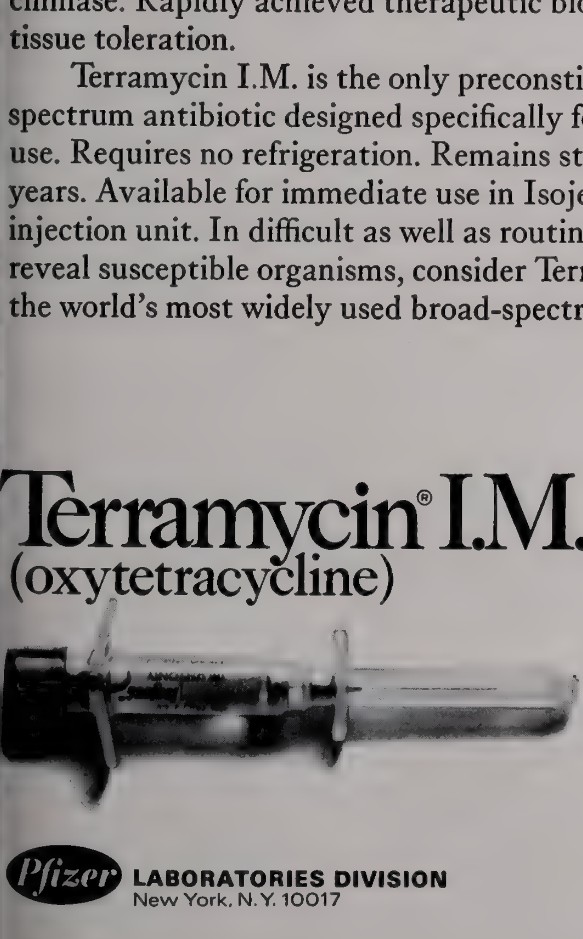
Terramycin®
(oxytetracycline)

Fire victim. Examination reveals second degree burn of lower leg. To combat shock, restore circulatory volume and replace protein loss, plasma is administered. Local pressure dressing applied. Limb elevated to limit the flow of lymph. About 36 hours after admission the patient develops an elevated temperature and complains of pain at the site of the lesion. Dressing removed. A suppurating slough area has developed over part of the burn. A swab specimen is taken for culture and the slough area is debrided. Antibacterial treatment is begun with Terramycin I.M. Days later, recovery is progressing, and the laboratory report shows a mixed infection with a predominance of susceptible coliform bacteria, confirming the therapeutic choice. Terramycin therapy is continued until all signs of infection disappear.

Experience has shown that Terramycin offers special advantages in treating bacterial infections complicating burns, when strains of causative organisms are susceptible. Broad-spectrum antibacterial coverage. Activity unaffected by penicillinase. Rapidly achieved therapeutic blood levels. Proven tissue toleration.

Terramycin I.M. is the only preconstituted broad-spectrum antibiotic designed specifically for intramuscular use. Requires no refrigeration. Remains stable for at least two years. Available for immediate use in Isoject,® a disposable injection unit. In difficult as well as routine cases, when tests reveal susceptible organisms, consider Terramycin. One of the world's most widely used broad-spectrums.

Terramycin® I.M.
(oxytetracycline)



Pfizer LABORATORIES DIVISION
New York, N.Y. 10017

Contraindicated: In individuals hypersensitive to any of the components of this drug.

Warnings: If renal impairment exists, even usual doses may lead to excessive systemic accumulation and possible liver toxicity. In such patients, lower than usual doses are indicated and for prolonged therapy oxytetracycline serum level determinations may be advisable.

Terramycin may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Use of oxytetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of teeth. This effect occurs mostly during long-term use of the drug, but it has also been observed in usual short-treatment courses.

During treatment with tetracyclines, individuals susceptible to photodynamic reactions should avoid direct sunlight. Discontinue therapy at first evidence of skin discomfort.

Note: With oxytetracycline, phototoxicity is not believed to occur and photoallergy is very rare.

Precautions: Use of broad-spectrum antibiotics occasionally may result in overgrowth of nonsusceptible organisms. Where such infections occur, discontinue oxytetracycline and institute specific therapy.

As with all intramuscular preparations, Terramycin Intramuscular Solution should be injected well within the body of a relatively large muscle. *Adults:* The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus), or the mid-lateral thigh. *Children:* It is recommended that intramuscular injections be given preferably in the mid-lateral muscles of the thigh. In infants and small children the periphery of the upper outer quadrant of the gluteal region should be used only when necessary, such as in burn patients, in order to minimize the possibility of damage to the sciatic nerve.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Increased intracranial pressure with bulging fontanelles has been observed occasionally in infants receiving therapeutic doses of the drug, but such signs and symptoms have disappeared rapidly on cessation of treatment with no sequelae.

Adverse Reactions: Subcutaneous and fat-layer injection may produce mild pain and induration which may be relieved by an ice pack. Very mild gastrointestinal disturbances, not requiring discontinuance of the drug, may occur occasionally. Allergic reactions, including anaphylaxis, rarely have been observed.

Dosage: *Adult:* The optimal dosage varies, depending on the type and severity of infection. Unless otherwise specified, a dose of 100 mg. every 8 to 12 hours, or a single daily dose of 250 mg. should be adequate for the treatment of most mild or moderately severe infections. In severe infections, 100 mg. every 6 to 8 hours, or 250 mg. every 12 hours may be necessary.

Serum levels obtained by the recommended dosages are comparable to those provided by the oral dosage of 1 to 2 Gm. daily in adults. Antibiotic therapy should be continued for at least 24 to 48 hours after all symptoms and fever have subsided.

In certain diseases specific courses of therapy may be recommended as a general guide. In primary and secondary syphilis for example, the daily administration of 2 Gm. oxytetracycline, orally, in divided doses for two weeks has given good results. In cases of gonococcal infection two intramuscular injections of 250 mg. each, or one intramuscular injection of 250 mg. combined with one gram given orally as a single dose, will usually suffice, but repetition of this therapy will be required in an occasional case.

In the treatment of hemolytic streptococcal infections, therapy should continue for at least 10 days to prevent development of rheumatic fever or glomerulonephritis. In the treatment of staphylococcal infections indicated surgical procedures should be carried out in all cases.

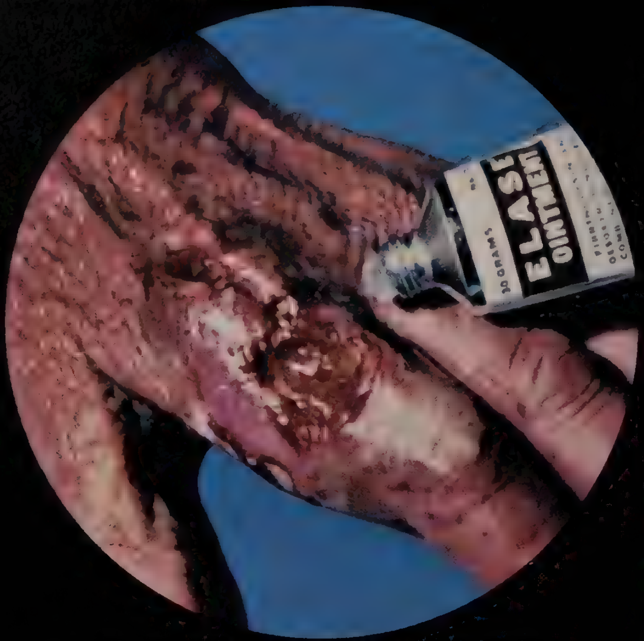
Pediatric: A dosage of 3 mg./lb./day in two doses has been found satisfactory in the treatment of most mild to moderately severe infections. For more severe infections, higher dosages may be indicated and should be adjusted accordingly.

Terramycin Intramuscular Solution provides maximum absorption and patient toleration with minimal local irritation.

Supply: Terramycin (oxytetracycline) Intramuscular Solution: available in single dose, prescored glass ampules containing 100 or 250 mg. oxytetracycline/2 cc., Isoject® syringes containing 100 or 250 mg. oxytetracycline/2 cc. and 10 cc. multiple dose vials containing 50 mg. oxytetracycline/cc.

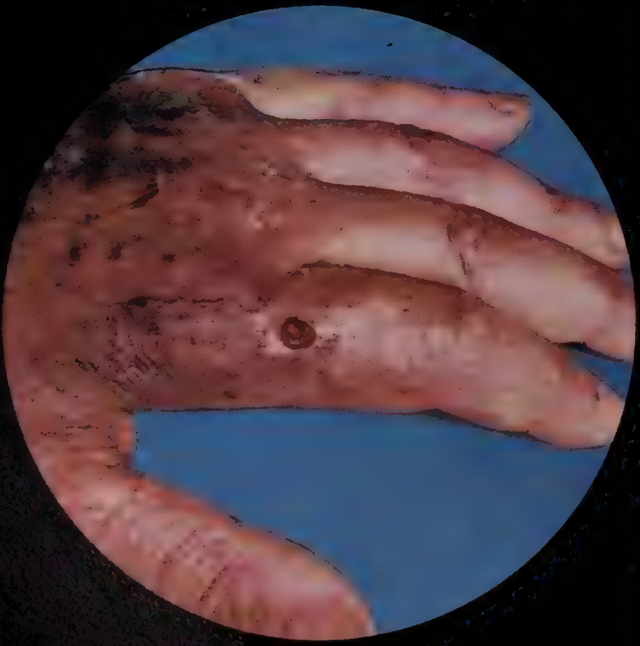
More detailed professional information available on request.

this ulcer did not heal...until its surface was cleared of dead tissue and debris



FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.



to aid in debridement to facilitate healing in chronic cutaneous ulcers...

Elase® Ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation...*for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris... the fibrin in blood clots, serum, and purulent exudates... and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

A New Low-Dose Combination Oral Contraceptive*

EDWARD T. TYLER, M.D.†
Los Angeles, California

SINCE 1956, THE Family Planning Clinics of Greater Los Angeles have been studying a variety of ovarian hormone contraceptive preparations. The first progestogen-estrogen combination that we employed was one containing 10 mg. of norethindrone with .06 mg. mestranol. Shortly after this we initiated investigations of a preparation containing 10 mg. of norethynodrel and .15 mg. of mestranol. Since that time we have used a variety of additional norethindrone-mestranol combinations, as shown in Table 1.

While most of the combinations listed have been clinically very satisfactory, we have been constantly striving to find the optimal ratios of progestogen and estrogen. A major reason for our continued investigations has been the undesired breakthrough bleeding and a few other side-effects common to all contraceptive hormonal agents. While in our experience breakthrough bleeding has been relatively low with norethindrone-mestranol 1/50, it is a little greater than has been our experience with the higher dose preparations. The ratio as well as the amounts of each hormonal ingredient in oral contraceptive tablets may play a significant role in the incidence of subjective side-effects. In an attempt to determine whether an increased amount of estrogen might make a difference, a clinical trial was begun about two years ago with a preparation containing 1 mg. norethindrone with .08 mestranol (1/80).‡

TABLE I
Family Planning Centers, Los Angeles

Sequence of Hormonal Doses			
Late 1940's —	Early 1950's	EE* (alone)	.05 mg.

‡Ortho-Novum 1/80 supplied for this study by the Ortho Research Foundation.

Nature of the Study

This report relates specifically to the results with this particular low-dose preparation during the first two years of trial. This new low-dose tablet is prescribed one tablet daily for 21 days beginning on the fifth day of the menstrual cycle. After the first cycle, the tablets are taken in the cyclic routine of "three weeks on-one week off."

Physically Normal Applicants

All patients in this study were women who requested oral contraceptives from the Family Planning Centers of Greater Los Angeles, California. Following complete examination of the breasts, abdomen and pelvis and standard routine laboratory studies, those patients found to be in satisfactory physical condition were included in this study. Those who needed specific attention medically were referred for that care and were not started in this program. Return visits were scheduled for every two, four and six months following the initial visit, and computer forms were filled in for subsequent analysis.

Computerized Data

On each return visit the patient's weight, symptoms, menstrual history and side-effects (if any) were noted and recorded. Repeat pelvic examinations were performed in cases of breakthrough bleeding, vaginal discharge or menorrhagia. Prior to initiating medication, Papanicolaou smears were collected from all patients who had not had smears taken elsewhere within a year.

Number of Cycles Studied

All patients admitted to this study were given an initial supply of tablets. A few did not return after the initial visit, and some made only one return visit thereafter; these are excluded from this report. Eight hundred sixty-two patients representing 4,211 cycles of therapy are included in this study. The average number of completed cycles per patient for the entire group was 4.9. The maximum number of cycles for a patient as of October 1968 was 15 (Table 2).

The patients were of an age range of relative maximal fertility, with 565 (71.7%) being between ages 16 and 27 years, while relatively few, 20 (2.8%), were over 40 years. The average age was 24.9 years. The fertile nature of this group is illustrated by the fact that 75.5% of these patients had had at least one full-term delivery prior to entering the study. Several of the remainder had had pregnancies which did not go to term.

Cycle Control

Maintenance of normal cyclic menstrual bleeding on oral contraceptives is important for many women.

TABLE 2
Cycles of Use Among Patients in Low-Dose Study

Last Cycle Completed	No. of Patients	% of Total	Total Cycles Completed	Total Pts. Per Cycle	Per Cent of Total
1	100	11.6%	100	862	20.5%
2	128	14.8%	256	762	18.1%
3	154	17.9%	462	634	15.1%
4	75	8.7%	300	480	11.4%
5	62	7.2%	310	405	9.6%
6	129	15.0%	774	343	8.1%
7	51	5.9%	357	214	5.1%
8	29	3.4%	232	163	3.9%
9	66	7.7%	594	134	3.2%
10	5	.6%	50	68	1.6%
11	5	.6%	55	63	1.5%
12	42	4.9%	504	58	1.4%
13	9	1.0%	117	16	.4%
14	5	.6%	70	7	.2%
15	2	.2%	30	2	%
Total	862	100.0%	4211	4211	100.0%

Average Number of Completed Cycles Per Patient—4.9 Cycles

Shorter Cycle

In this study the average pre-therapy cycle length was 27.9 days, while the average therapy cycle length was 27.1 days, suggesting an apparent tendency to somewhat shorter cycles. But it should be noted that in questioning patients about their reliability in taking tablets 36.5% (31 of 185 patients) of those showing cycle lengths of less than 25 days had in fact taken tablets incorrectly (Table 3).

TABLE 3

Comparison of Pre-Therapy Cycle Length with Therapy Cycle Length

Pre-Therapy Cycle Length	No. of Patient Cycles	Per Cent of Subtotal	Average Therapy Cycle Length
Irregular	68	1.9%	27.4
Less than 21	18	.5%	27.1
21-24	128	3.6%	27.1
25-26	221	6.3%	27.0
27-29	2511	71.2%	27.1
30-35	580	16.4%	27.2
36-42	3	.1%	27.0
Subtotal	3529	100.0%	
Not comparable	682		
Total	4211		

Average Pre-Therapy Cycle Length 27.9 Days

Average Therapy Cycle Length 27.1 Days

Shorter Flow

A comparison of days of flow before and during therapy reveals that prior to therapy 25.9% of the cycles had a duration of four days of flow, 38.1% a duration of five days. During therapy these figures were reversed in trend to 48.8% and 20.4%, suggesting a mild to moderate decrease in duration of flow. Pre-therapy average was 4.6 days and during therapy, 3.9 days (Table 4). Of the total cycles evaluated 233 (5.5%) were not subject to comparison.

TABLE 4

Comparison of Pre-Therapy with Therapy Days of Flow

	Total	Per Cent
Decrease	1909	45.3%
No change	1266	30.1%
Increase	522	12.4%
Not comparable	514	12.2%

Average Days of Flow Pre-Therapy 4.6 Days

Average Days of Flow During Therapy 3.9 Days

Diminution of Bleeding

Categorizing the amount of flow subjectively as "not stated," "none," "light," "moderate" and "heavy" and assigning these values of 0 to 3, our data indicates that average pre-therapy amount of flow was 2.0, while average amount during therapy was 1.9. Thus, the figures for both duration and amount of flow would suggest a slight diminution in bleeding while on this therapy. This would ordinarily be considered a positive side-effect.

Side-Effects

Spotting

Side-effects that occurred were minimal and of little consequence. It was noted that 62 patients (7.2%) reported spotting during therapy, for a total of 81 cycles (1.9% of cycles). Eleven of these 62 patients reported incorrect tablet-taking during cycles of spotting. Spotting gradually decreased with each cycle. Regarding breakthrough bleeding, this similarly occurred more in the earlier cycles, with an incidence of 1.9% of the total 4,211 cycles, and with 67 patients of the 862 (7.8%) experiencing this during a total of 44 cycles. In 10 cycles this was associated with incorrect taking of the tablets.

Lessening of Dysmenorrhea

Dysmenorrhea, which was a complaint in almost half of the women prior to therapy, was improved in 38.2% of the cycles of therapy, unchanged in 45.7%, increased in only 1.5%; and findings were not comparable in 8.3%. Thus it may be stated in general that the therapy apparently was associated with improvement in dysmenorrhea in a substantial number of cycles.

Decreased Tension

Pre-menstrual tension occurred in about one third of pre-therapy cycles, and during therapy there was a decreased incidence of it in approximately 85.4% of those previously complaining of it.

Gastrointestinal Disturbances

The incidence of gastrointestinal disturbances was very low in this study. Nausea was reported in practically only the first three cycles, 12 patients experiencing it in the first cycle, six in the second, and three in the third. The total number of cycles associated with gastrointestinal disturbances was 29 of 4,211 (incidence of 0.7%). The patient incidence in the total 862 evaluated was 20 or 2.3%.

Weight Change

In weight changes the percentage of patients showing gain (45.9%) and loss (38.6%) was very similar. No weight change was reported in 15.5%; on 256 patients in the group no comparable data were available (Table 5).

A representative sample of patients was used to measure pituitary-ovarian function, liver function, adrenal function, and effects of this combination estrogen-progestogen on cervical mucus.

TABLE 5
Comparison of Pre-Therapy Weight with Last Reported Therapy Weight

	Weight Gain	Weight Loss	Total	% of Subtotal
No change in weight			94	15.5%
1-5 pound change	195	160	355	58.6%
6-10 pound change	55	56	111	18.3%
11-15 pound change	17	11	28	4.6%
16 & over pound change	11	7	18	3.0%
Subtotal	278	234	606	100.0%
Per cent of comparable patients	45.9%	38.6%		
Patients not comparable			256	
Total in study			862	

Urinary gonadotrophin determinations were done on 10 patients. All determinations were within normal limits. Twenty-four hour urine collection was made for four consecutive days on each of 12 patients, who on the third day were given 750 mg. metapirone every four hours. The responses to metapirone were normal in every case tested.

The finding of luteal-type cervical mucus on 22 patients suggests an additional contraceptive effect. This type of mucus tends to inhibit spermigration.

Effectiveness

One pregnancy, which was unplanned, occurred during this study in 4,211 cycles, or 351 women-years. This suggests a pregnancy rate of 0.28, which is one of the lowest reported for any of the oral contraceptives.

Summary

It appears that on the basis of the number of women studied, the degree of effectiveness, and the relatively low incidence of side-effects that a preparation containing a low-dose of norethinedrone 1 mg. with mestranol 0.08 mg. is a very good oral contraceptive.

Vision

A man once found a shiny new dime in the road. From then on his mind was focused on small things and he never lifted his eyes from the ground while walking. At the end of forty years, he accumulated 34,947 buttons, 54,712 pins, 11 pennies, a bent back and a bad disposition. He lost the glories of the light, the smiles of friends, the beauties of nature, and the opportunity to serve his fellowmen and spread happiness.*

---

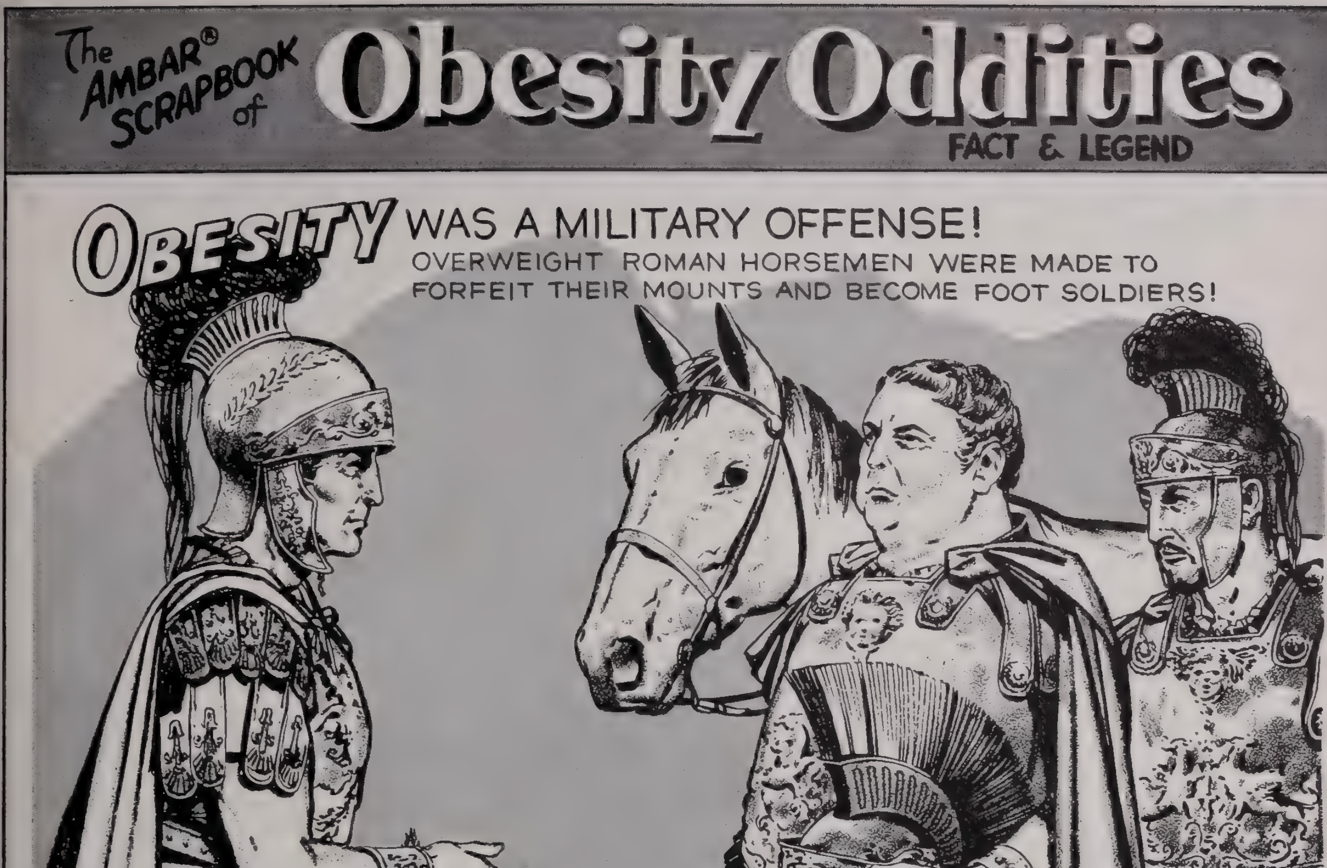
*Alexander Co-operator.

Values

The Arab was telling of the time he had lost his way in the desert. Just as he was about to abandon hope and let his hunger overcome him, he found a bag of pearls. "I shall never forget," he said, "the relish and delight I felt supposing the contents of the bag to be dried wheat, or the bitterness and despair I suffered in discovering that the bag contained nothing but pearls."*

---

*Red Barrel.



The AMBAR® SCRAPBOOK of
Obesity Oddities
FACT & LEGEND
OBESITY WAS A MILITARY OFFENSE!
OVERWEIGHT ROMAN HORSEMEN WERE MADE TO FORFEIT THEIR MOUNTS AND BECOME FOOT SOLDIERS!
RECORDED ON AN ENGLISHMAN'S TOMBSTONE
JAMES PARSON
DIED 1743
HE HAD OFTEN EATEN A WHOLE SHOULDER OF MUTTON AND A PECK OF HASTY PUDDING

Ambar No. 2
Extentabs
℞
THE COST OF AMBAR EXTENTABS IS APPROXIMATELY ONE HALF THAT OF OTHER LEADING APPETITE SUPPRESSANTS
AN IMPORTANT FACTOR IN LONG TERM THERAPY

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

A·H·ROBINS

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol. An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take. PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Book Reviews

That is a good book which is opened with expectation and closed with profit.
—Alcott

PRACTICAL PSYCHIATRY FOR INTERNISTS —Douglas Goldman, George A. Ulett; C. V. Mosby, 1968; 168 pp. $9.85.

Internists are aware of the heavy percentage of neurotic and psychiatric problems among their patients. In my practice about 75% of the patients are seen for such difficulties. If one adds those with "organic" complaints, but who also have important psychological aspects, the figure approaches 100%. This book is a primer written by psychiatrists for internists and general practitioners. Its brevity, 168 pages, commends itself to busy physicians. Occasionally it is too brief. In their attempt to put across the idea that emotional influence induce the formation of gallstones, the case histories the authors adduce are confined to the statement that three female employees (of the offending cholelithogenic physician) and his maid *required* cholecystectomies. It is unfortunate that this book, which contains so many concepts so important to internists, should also contain such untenable ideas as this gallstone theory. Collaboration with a physician would have at least required that their thesis be defended with enough data to establish the pathological facts. Did the girls have gallstones?

The chapter on frank psychiatric disorders with numbers keying the diagnoses to the International Classification of diseases will interest chiefly those preparing for examination in the field.

Hypnosis in medicine is briefly discussed. The book can serve a useful purpose to internists and others who must learn to appreciate the major aspects of psychiatry in medicine.

WHAT YOU CAN DO ABOUT CANCER. Joseph C. Maroon, M.D., Doubleday & Co., Inc., 1969. Price: $5.95.

This is a well-written book by a physician giving some interesting facts about some of the most commonly encountered types of cancer. At the end of each chapter he provides answers to some of the most commonly encountered questions. This book should provide its greatest value to the lay reader of medical topics.

Carl O. Rice, M.D.
Minneapolis, Minnesota

MASTERS OF MEDICINE, AN HISTORICAL SKETCH OF THE COLLEGE OF MEDICAL SCIENCES, UNIVERSITY OF MINNESOTA, 1888-1966.

A 940-page history of the University of Minnesota's College of Medical Sciences has been published—the culmination of six years' research and writing by its author, Dr. Jay Arthur Myers, professor emeritus of internal medicine and public health.

The work, which includes some 245 pictures—was made possible by a $20,000 gift from Dr. Frank McKinney to the Minnesota Medical Foundation. Dr. McKinney, a Minneapolis surgeon, practiced with Dr. Myers, a 1920 graduate of the University's Medical School.

DYSLEXIA: DIAGNOSIS AND TREATMENT OF READING DISORDERS. Edited by Arthur H. Keeney, M.D., and Virginia T. Keeney, M.D. C. V. Mosby Company, St. Louis. 1968. Price: $12.00.

During the last two years remarkable advances have been made in the knowledge of diagnosis and treatment of reading disorders. The physician, educator, or therapist seeking new knowledge in the field of dyslexia had previously been required to search the literature in a wide range of fields to come across the published papers. "Dyslexia," which is a summation of a National Conference on dyslexia held at Philadelphia, Pennsylvania, fills a great need for such individuals who require current up-to-date knowledge on this subject. The fourteen authors who contributed to this volume write with a uniformity and clarity which indicates careful editing. General areas include definition, etiology, pathophysiology, clinical detection, treatment, and psychological problems, and finally a discussion of topics worthy of research.

The summary of discussions, "Questions and Answers," points out problems not fully appreciated by the authors and the need for new areas of research and endeavor. By large, this is an excellent book and worthy of study by all physicians and paramedical workers who deal with children with a reading disability.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

For elderly patients
in need of a mild tranquilizer
consider **Tybatran**®
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

Save him from

RHEUMATIC FEVER

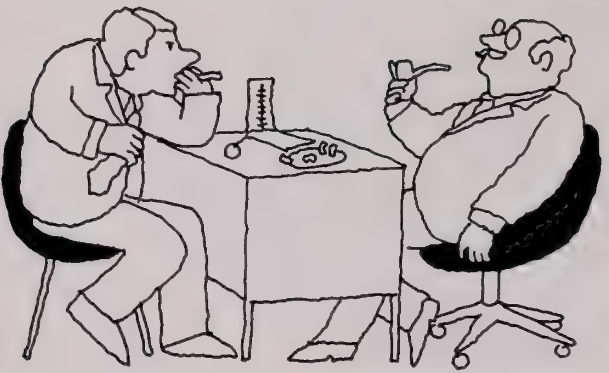
Here are two ways:

1. If your child has a bad sore throat, don't wait — it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

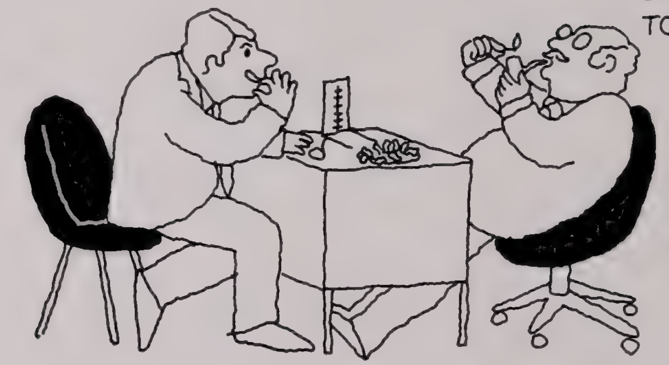
2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...
so more will live
HEART FUND

The Apprehensive Hypertensive



WELL, YOU HAVE WHAT WE CALL MODERATE HYPERTENSION– HIGH BLOOD PRESSURE. NOW I DON'T WANT YOU TO WORRY, BUT WE ARE GOING TO HAVE TO CHANGE A FEW LIVING HABITS. FIRST, WE'RE GOING TO HAVE TO CUT OUT SMOKING–ALTOGETHER.

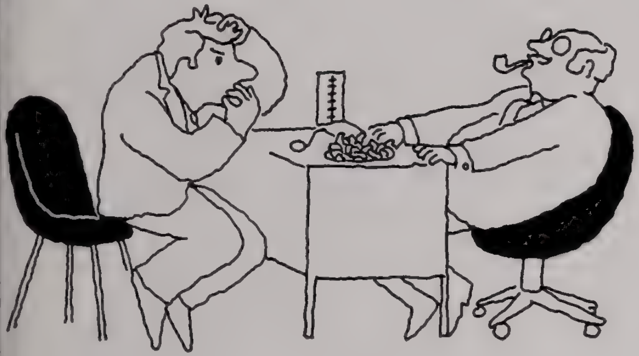


THEN WE HAVE TO LOSE WEIGHT. 20 POUNDS SHOULD DO IT... WE'LL TALK A LITTLE LATER ABOUT THIS DIET WE'RE GOING TO START.

Regroton® to lower blood pressure

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Regroton®: chlorthalidone 50 mg., reserpine U.S.P. 0.25 mg. *Indications:* Hypertension. *Contraindications:* History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. *Warning:* With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increase respiratory secretions, nasal congestion, cyanosis and anorexia ma occur in infants born to reserpine-treated mothers. *Precautions:* Antihypertensive therapy with this drug should always be initiated cautiousl in postsympathectomy patients and in patients receiving ganglioni blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. T avoid hypotension during surgery, discontinue therapy with this agen two weeks prior to elective surgical procedures. In emergency surgery use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression o renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma ma be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy the drug should be discontinued and potassium supplements given provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receivin



WE'VE GOT
PROBLEMS.

and allay anxiety in hypertension

corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. *Adverse Reactions:* The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. *Average Dosage:* One tablet daily with breakfast. *Availability:* Pink, single-scored tablets in bottles of 100 and 1000. (B)46-600-C

RE-6742

This year why not invite your overseas friends over here?

Too expensive for them?

Maybe not, this year.

Because, this year, there are made-to-order bargains to lure them here. Bargains in trans-ocean sea fares, and air fares, just-for-them. And reduced bus, rail, and air rates, once they arrive.

And lots more. But some of them may not be available next year. And many of them must be arranged before your friends leave the other side.

So write to them. Tell them to talk to their travel agent or overseas carrier. (That way, they can get all the details.)

Then add one more thing. Tell them America is not so big and bustling that no one will have time for them—and you'll be around to show them the ropes when they arrive.

Now sit back and wait. With any luck, you may soon be showing them America as you see it. But better be prepared for one surprise.

You may soon also be seeing America as they see it—rediscovering it through their wide and startled eyes.

Minnesota Medicine at a Glance

Anesthesia after Myocardial Infarction—*Tarhan and Moffitt* Page 1733.

The steps to avoid operational and postoperative cardiac complications are discussed in this concise article concerning the high-risk patient with a recent myocardial infarction.

Hepatic Coma—*Lindall et al.* Page 1737.

The authors report the case of a pregnant patient successfully treated by multiple exchange transfusions for a fulminant hepatic coma secondary to infectious hepatitis. Although 82 cases of hepatic coma have been treated by exchange transfusion, this is only the second case reported in pregnancy. In addition to the exchange transfusions, conventional measures were also employed.

Coronary Care in a Small Hospital—*Anderson* Page 1741.

An intensive coronary care unit (ICCU) was established in a very small community hospital whose staff was made up of eight private practitioners, all generalists. A mortality of 18% was observed in 33 cases of acute myocardial infarction as compared to a mortality of 46% in 24 cases during one year prior to the establishment of the ICCU. The unit was used for 52 other patients during the year who likewise benefited from the intensive care. The very small community hospital can develop and effectively operate a coronary unit with gratifying results.

Prolonged Oxygen Therapy—*MacDonald et al.* Page 1745.

Distinctive morphologic pulmonary lesions associated with prolonged oxygen therapy at high concentrations were observed in 20 patients who came to autopsy in 1966, nineteen of whom had had assisted ventilation for three to 120 days. The 20th patient had breathed for four days from a mask which delivered 100% O_2. All had an inappropriately low partial pressure of oxygen in their arterial blood.

Histologically, the distinctive pattern in the lung included intra-alveolar deposits of fibrin, hyaline membranes, thickened intra-alveolar septa, prominent alveolar lining cells, and chronic inflammatory cellular infiltrate of variable degree. This morphologic pattern was not associated with pulmonary edema, organizing pneumonia, and bronchopneumonia of various etiologies.

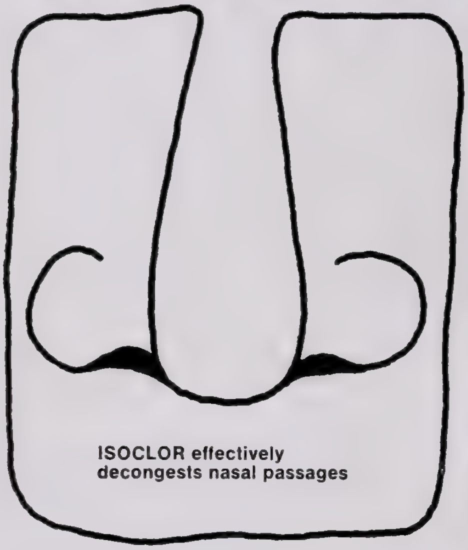
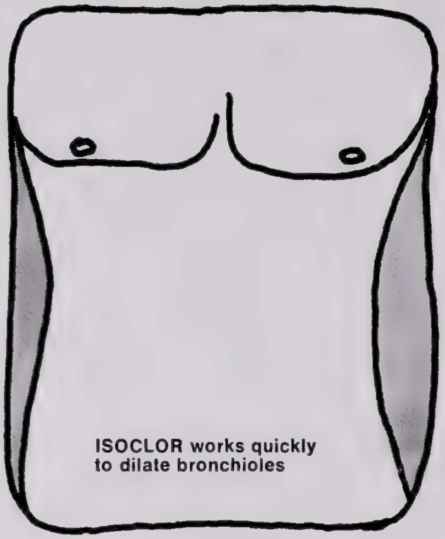
Special Issue
Minnesota Radiologic Society

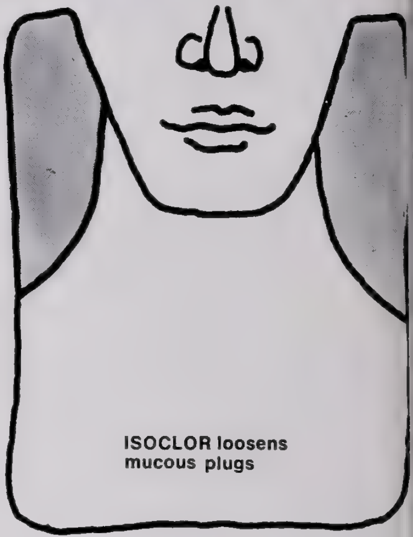
HERE ARE THE COLD FACTS:



ISOCLOR effectively decongests nasal passages

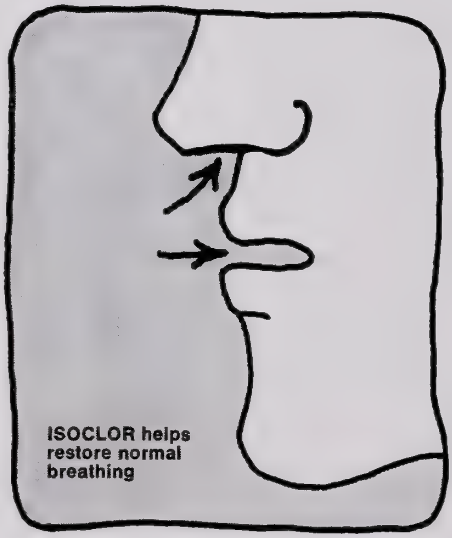


ISOCLOR works quickly to dilate bronchioles



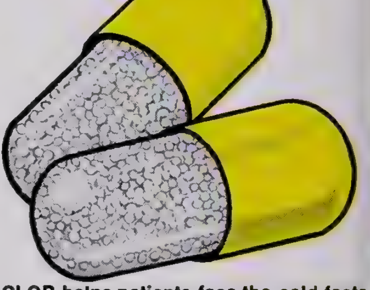
ISOCLOR loosens mucous plugs

ISOCLOR relieves runny eyes



ISOCLOR helps restore normal breathing

ISOCLOR promptly and effectively combats symptomatic miseries of the common cold and influenza



ISOCLOR helps patients face the cold facts

ISOCLOR®

Isoclor provides quick, long lasting relief of respiratory congestion and discomfort brought on by common colds, influenza, and allergies. Isoclor contains chlorpheniramine maleate — one of the most potent and safest antihistamines. And pseudoephedrine HCl — a decongestant bronchodilator providing effective and long lasting relief for the entire respiratory tract. Both work to extend the range of relief.

COMPOSITION: Each tablet or 2 teaspoonfuls of liquid contains:

Chlorpheniramine Maleate	4 mg.
Pseudoephedrine HCl	25 mg.

Each ISOCLOR Timesule contains:

Chlorpheniramine Maleate	10 mg.
Pseudoephedrine HCl	65 mg.

In a special pellet form providing both prompt and sustained effect.

INDICATIONS: For symptomatic relief of colds, hay fever, allergic conjunctivitis, perennial rhinitis of allergic origin and sinusitis. Opens nasal, sinus and bronchial passages orally.

CONTRAINDICATIONS: Sensitivity to antihistamines or sympathomimetic agents. Severe hypertension or severe cardiac disease.

PRECAUTIONS: Use with caution in patients suffering with hyperthyroidism. Patients susceptible to the soporific effects of chlorpheniramine should be warned against driving or operating machinery should drowsiness occur.

CAUTION: Federal law prohibits dispensing without prescription.

SUPPLIED: Tablets: Bottles of 100 and 1000. Liquid: 4 oz. bottles, pints, and gallons; Timesules: Bottles of 50, 250, and 1000.

DOSAGE AND ADMINISTRATION:	Tablets	Liquid	Timesule
Adults:	1 q. 4 h.	2 tsp. q. 3-4 h.	1 q. 12 h.
Children 6-12 years:		1 tsp. q. 3-4 h.

he may be a candidate for

DECLOSTATIN® 300 b.i.d.

Demethylchlortetracycline HCl 300 mg
and Nystatin 500.000 units
CAPSULE-SHAPED TABLETS Lederle

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Effectiveness: Because its antibacterial component is DECLOMYCIN Demethylchlortetracycline, DECLOSTATIN should be equally or more effective therapeutically than other tetracyclines in infections caused by tetracycline-sensitive organisms. The antifungal component, Nystatin, protects against superinfection by antibiotic-resistant fungal overgrowth (particularly monilia) in the intestinal tract.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization—provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste—confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[1]

Concomitant relief of G. I. gas distress—provided by the proven antiflatulent action of simethicone.[2]

Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonfuls to be taken between meals and at bedtime, or as directed by physician.

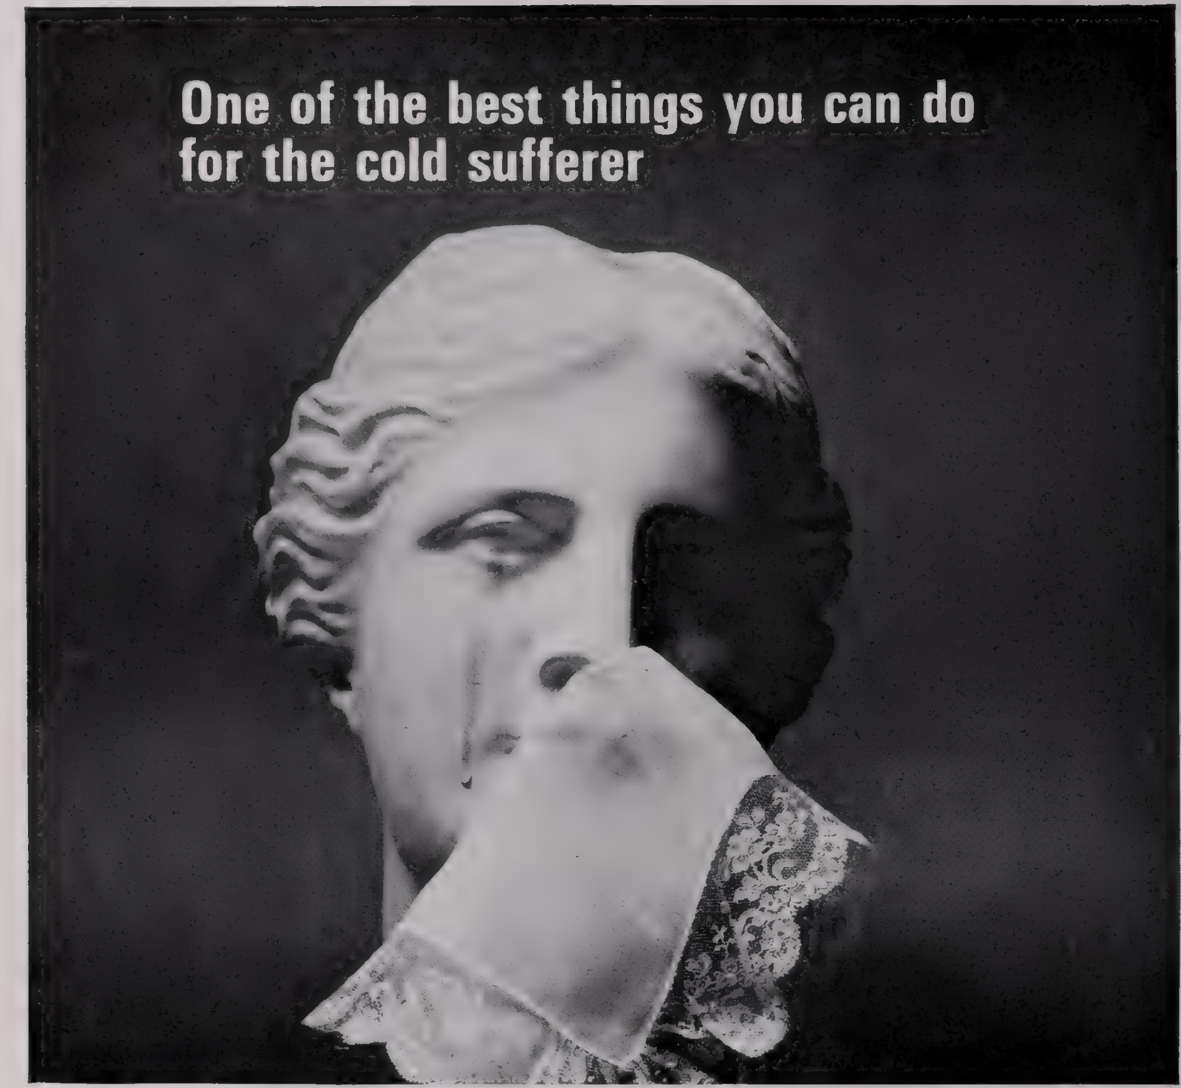
President
Minnesota Radiological Society

See the President's Letter, Page 1855.



One of the best things you can do
for the cold sufferer

Ornade® Spansule®

brand of
sustained release capsules

Trademark
Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

Prompt relief from nasal congestion and hypersecretion due to colds.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction.
Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.
Usage in Pregnancy: Use in pregnancy, nursing mothers and women who might bear children only when potential benefits have been weighed against possible hazards.
Note: The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.
Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible adverse reactions of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, incoordination, tremor, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported.
Supplied: Bottles of 50 capsules.

One capsule q12h for round-the-clock relief

President's Letter

Identity

Preoccupation with identity has pervaded religious and philosophical thought throughout recorded history.

The radiologist is now engaged in a struggle for professional identity—to be associated with the family doctor, surgeon, and other specialists in the eye of the general public.

Recognition of the radiologist's worth and place in medical practice has been well established within the profession.

Outside the profession few are informed as to his area of knowledge, skill, and discipline, and how it applies to them as patients. This has been the fault of the radiologist himself for following the path of least resistance and allowing the hospital to front for his activities and to collect for his services under the broad heading of "X-rays" or "X-ray Department."

A national movement by radiologists, given urgency by the Medicare legislation, got under way in July, 1966, whereby the radiologist has emerged from anonymity by billing directly for his services. This has by no means been embraced by all the specialty; but the way has been shown, and the results are heartening and satisfying.

It is only right that the radiologist should bear the responsibility for his fees, his diagnoses, and his decisions. It is only right that the affected person know where the responsibility rests. It is only just that none hide behind the hospital facade and let the public get the mistaken idea that the hospital can practice medicine. This is truth in packaging.

"The hospital is primarily a building in which patients are housed, fed and rendered medical care by physicians and their technical assistants."* When the public knows who the radiologists and other hospital-based specialists are and that their technical assistants are of necessity trained by the medical profession, there will be no confusion as to who administers health care: the hospitals or the doctors.

It is up to us to do our best to set the record straight through the most direct and professional relationship possible, established by direct billing. This in turn means public education: billing, collecting, and explaining. We are remiss if we do not have a printed explanation and a place where our representatives can explain to the public and establish rapport, understanding, and good will.

I have been rarely thanked by the patient for finding pathology, but I now have the satisfaction of being known in my community. Our egos need feeding, too, and we must be prepared to accept blame as well as credit. "Triumph and Disaster", the two imposters of Kipling's poem, are none the less life ingredients.

Now the final step has been taken in the search for identity, and the patient has been billed for services rendered by the doctor rendering the service. This, more than any other factor, has established the relationship of the practice of radiology to the practice of medicine and identified the radiologist with the physician.

Out of this is emerging a newly earned sense of self-respect with a growing public awareness of the radiologist and the part he contributes to the practice of medicine.

The Appearance of Iliac Crest Epiphysis

An Indicator of Gonadal Dysfunction

DONALD E. DIETRICH, M.D.[*]
St. Paul, Minnesota

OSSIFICATION AND closure of the iliac crest epiphysis has often been reported to be an indicator of gonadal function. Other epiphyses which appear in adolescent years, but which have not received the attention of the iliac crest, include the ischial tuberosity, the os acetabulum of the hip, the acromion of the clavicle and accessory epiphyses, the coracoid process of the scapula and the epiphyses of the fingers.[7,13] The purpose of this paper is to emphasize the relationship of the iliac crest epiphysis to gonadal dysfunction.

Numerous authors have concluded that ossification of the iliac crest epiphysis is related to puberty. In 1942 Buhl and Pyle[7] suggested that onset of ossification of the crest of the ilium might be used as a maturity determinator in adolescence, inasmuch as it occurred within six months of menarche[†] in two thirds of girls. They also determined that boys follow girls in this sequence of ossification by an average of 1.6 years. In 1961 Hewitt and Acheson[17] concluded that maturation of the pelvis is more responsive to the hormonal changes of puberty than that of the femur. Palma et al. in 1967[25] established that ossification of the iliac epiphysis occurs at puberty, during the year of maximum growth, plus or minus a year. They found that this epiphysis was present in the majority of girls having spontaneous or therapeutically induced menstrual periods. "This indicates that its appearance is an index of hormonal modification peculiar to puberty." Garn, Rohmann and Silverman[13] stated that in puberty more attention must be given to the hip and the sesamoids of the thumb and other fingers, and Silverman[31] concluded that iliac crest ossification occurs in a significant population within six months of the onset of puberty, and that fusion with the primary centers occurs within a few years following ossification development.

Numerous authors have offered standards of postnatal ossification and closure[1,7,8,10,11,13,14,18,23,26] and many tables are extended to include adolescent years. Statistically, Garn, Rohmann and Silverman[13] have determined the median and significant deviation of most ossification centers. The chronological age of appearance of the iliac crest epiphysis is given in Table 1.

The Functional Prepuberal Castrate Syndrome (Testicular Agenesis)

This syndrome is unique as it affords an opportunity to visualize by x-ray the effect of testosterone on epiphyseal centers. Patients are male phenotypes* who have not developed normal testes. Biopsy may reveal remnants of wolffian duct derivatives or hyalinized prepuberal testes.[35] There is a secondary delay in skeletal maturation, and these patients exhibit greater growth in the lower half of the body. They show failure of development of the external genitalia as well. Since gonadal tissue is not present there is no response to endogenous or exogenous gonadal stimulation.[15]

Case Report

A 28-year-old man presented himself for a premarital physical examination, stating that libido was satisfactory. An excretory urogram was requested as part of the medical workup and, because of radiographic findings, further studies were undertaken (Figures 1, 2, 3).

Past history was that at age seven he was suspected of having bilateral undescended testes but at surgery was found to have congenital nondevelopment of both testicles. During his early years he was of small stature but, at about age 13, a growth spurt was noted; at age 18 he was six feet tall and at 21, six feet, three inches, weighing 220 pounds. He denied weakness or color blindness and stated that he shaved two or three times a week.

Family history was unremarkable. His mother was twenty years of age at the time of the patient's birth.

Physical examination revealed a moderately obese Caucasian male with a boyish face and a high-pitched voice; height 76 inches, total breadth of arm span 79 inches.

There was no chest hair, sparse axillary hair and a female escutcheon.

The penis was atrophic; no palpable testes or herniations were detected. Roentgenograms (Figure 1) reveal moderate ossification of the iliac crest epiphysis but no fusion. There is a borderline metacarpal sign (Figure 2) but no evidence of genu valgum. Laboratory findings are listed in Table 2 and Figure 3.

After eight months of oral testosterone medication, his shaving habits have increased from two or three times a week to daily. Follow-up x-rays revealed only slight improvement in right iliac crest epiphysis.

Hypogonadism

No available classification of hypogonadism is entirely satisfactory or complete, but gonadal dysfunction is usually classified into two main groups: 1, Primary gonadal deficiency with elevated gonadotropin, and 2, hypothalamic or pituitary insufficiency.

Eunuchoidism is seen in both sexes, though decreased function is more often found in the female.[5] Most frequently eunuchoidism results from surgical removal of gonads in childhood or from a disorder which causes the gonads to atrophy or be destroyed before puberty.[9] It has

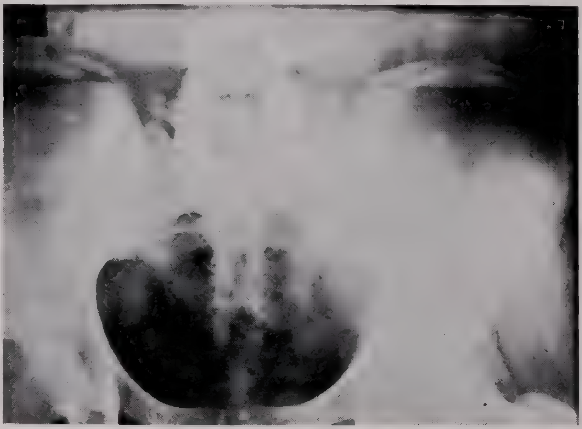

Fig. 1—Epiphysis of iliac crest at age 28—an indication of gonadal dysfunction, A-P, pelvis.

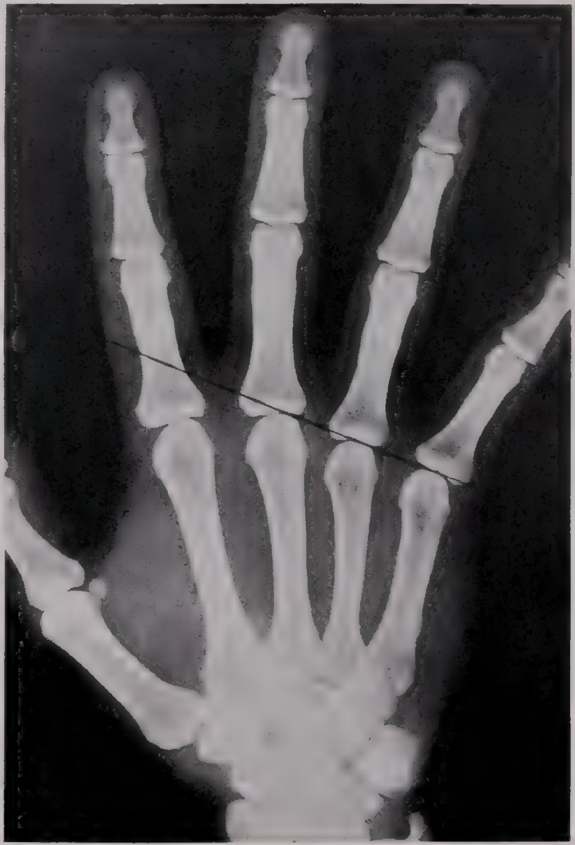

Fig. 2—Metacarpal sign—borderline. A-P, right hand.

---

*See Test Your Word Score Page 1921.

been established that as a result of gonadal androgen deficiency in childhood, there is delay in epiphyseal closure, resulting in retarded maturation.[15] The effects of maturation are greater than on linear growth.[34]

Castration

The experimental effects of castration on the mammal depend upon the age when the operation is performed. Thus, if gonads are removed before puberty, accessory sex organs and secondary sex characteristics fail to develop and there is a greater deposition of fat. It has been recognized that castration of boys prior to puberty retards ossification of the epiphysis of the long bones; the persistence of epiphyseal synarthrosis* creates a disproportionment characterized by lengthening of the lower limbs[5,30]

Associated Disorders

Hypogonadism may be accompanied by varying degrees of gynecomastia, cryptorchidism and menstrual abnormalities as well as delayed puberty. It is often part of such disorders as the Laurence Moon Biedl syndrome, mental defectiveness, Friedreich's ataxia, myotonia dystrophica, progressive muscular dystrophy, amyotonia, Werner's syndrome, dyskeratosis congenita (Zentrical-Cole-Engman's syndrome), ichthyosis, etc.[15]

Endocrine Dysfunctions

The determination of urinary gonadotropins will differentiate pituitary from primary testicular or ovarian dysfunction. The determination of 17-ketosteroids is popular but has little value inasmuch as 70% originates from precursor secreted by the adrenal cortex; hence, this is not a true test of testosterone or estrogen production.

Plasma and Urine

Plasma and urinary testosterone levels permit a specific assessment of Leydig cell function. These values have increased our understanding of hypogonadism and secondary effects[24,29,35]; when Leydig cell function is deficient, androgen replacement therapy is indicated.

Numerous studies have shown that estrogens in large amounts will artificially decelerate growth in rodents and humans.[2,30,35] In gonadal dysgenesis, because of lack of estrogen, growth continues through puberty for a longer period than in a girl who feminizes. When estrogen is lacking, the extremities tend to be excessively long and the patients may be tall, implying delayed epiphyseal closure in the female. When estrogen substitution therapy is used, as in the artificial deceleration of growth, the effect is not immediate but growth tends to be decelerated. If such a patient is dwarfed, however, it is advisable[35] to defer substitution therapy for as long as possible in order to achieve maximum stature.

Urinary estrogen excretion products and the plasma levels of estrogen determined by chromotography are valuable research techniques; however, the expense of these studies renders them impractical.[35]

Hypergonadism

Accelerated Maturation

With increased gonadal function, there is accelerated maturation, and dwarfism can result from early closure of the epiphyseal centers.[3] Although the direct mechanism is not known, androgens are known to support osteoblastic elaboration of octeoid, thus stimulating endochondral as well as intramembranous bone growth.

Precocious Puberty

Often the true cause of precocious puberty is unknown. Accelerated maturation is present in the adrenogenital syndrome.[5] A condition which causes sexual precocity in females and deserves special consideration is the granulosa cell tumor of the ovary. Five percent of patients with this condition are under fifteen years of age and experience accelerated maturation with advanced bone age.[9] Precocious puberty may also be seen with rare adrenal cortical tumors, ovarian tumors and hypothalmic lesions.[19,35] Patients whose ovaries are stimulated by gonadotropin have advanced bone age and excessive growth. However, the advancement of bone age is usually not as great as it is in children who have large amounts of estrogen produced by tumors.[35] Albright's syndrome may be associated with precocious puberty in the female. In these cases also, there may be early appearance of ossification centers and closure so that growth stops—often resulting in dwarfing of stature.[9]

Gonadal Dyscrasias

Recent rapid expansion of knowledge in genetics has brought to the radiologist's attention a number of disorders associated with aberrations of chromosomal constitution. Radiographic findings have been summarized by numerous authors[12,16,21,22,24] There are differences of opinion in the literature as to whether or not there is delayed osseous maturation accompanying gonadal dysgenesis.[23]

Seminiferous Tubular Dysgenesis

Klinefelter's syndrome (seminiferous tubular dysgenesis) (XXY) is possibly the commonest cause of infertility in man, and the eunuchoidal features are often first found in puberty.[15] Tanner feels that the skeletal proportions cannot be attributed to delayed epiphyseal fusion since skeletal maturation follows a normal male pattern.[34] Thus, even the "eunuchoidal Klinefelters" may have a normal skeletal age, though some are retarded. Laboratory results usually indicate that excretion of urinary gonadotropin is increased, whereas plasma testosterone levels are generally in the low normal range, or even lower.[35]

Gonadal Aplasia

The short stature of Turner's syndrome (gonadal aplasia) is invariably present in XO individuals, and this has usually been attributed to a genetic factor.[4,21,25,28] Skeletal maturation is normal or only slightly delayed in childhood, but the delay increases in adolescence.[25,35] Acheson and Zampa[2] found that the majority show arrest in skeletal maturation.

Miscellaneous

In familial osteochrondrodystrophy (Morquio's syndrome*) and some of the chondrodysplasias, whole groups of centers may fail to appear,[13] and in epiphyseal dysostosis*, epiphyseal centers are often delayed.[32]

---

*See page 1880.

When there is a deficiency of gonadal hormones, steroidal substitution therapy has been used successfully in many of these patients.[4,24,34]

Discussion

The determination in childhood of skeletal maturation relative to chronological age is well accepted. Standards offer a broad range of normal since the curves are rather flat and smooth. This is because the healthy population in the United States is made of heterogeneous individuals who differ widely in color, race, constitution and development. The great variability in the curves has prompted many radiologists to favor a multipart approach in maturation determination, assuming that the entire body must reveal more than just a single part.

Garn, Rohmann and Silverman demonstrated that selected centers of the hand, the foot and the knee contribute the most objective information on skeletal development during the first ten years of life. Many factors influence this development. Chromosomal effect is manifest very early. It is known for example that the male is retarded relative to the female, and the action of the Y chromosome probably begins at about seven intra-uterine weeks. Growth hormone and thyroid influence appear to have their greatest effect on centers which develop during infancy and childhood.

Garn, Rohmann and Silverman have stated that in puberty more attention must be given to centers of the hip and sesamoids of the thumb and other fingers. The present case revealed the iliac crest epiphysis as the only radiologically important finding and illustrates the relationship of this epiphysis to abnormal gonadal development occurring in an otherwise normal male (XY).

It was established by Elgenmark that in infancy, height shows a stronger correlation with ossification center development than age does; while later on, the correlation is largely equal. One might speculate in considering the eunuchoid habitus, whether the ossification of certain "androgen-dependent epiphyses" would not correlate equally with age and height.

The value of information on skeletal development must be weighed against the radiation cost, since radiographs of the hip may contribute to gonadal radiation. Pelvis roentgenograms should not be routine.

Since a delay in ossification and closure may radiographically reflect gonadal insufficiency, early closure may thus be used as an indicator of precocious puberty. When ossification or closure of the iliac crest epiphysis exceeds the normal range, it should be suspected that gonadal dysfunction is present. Other radiographic findings will help differentiate genetic dyscrasia from endocrine dyscrinism, and specific laboratory data now available will aid in establishing the definitive diagnosis.

Thou shalt not kill; but need not strive officiously to keep alive.—Clough

A Patriarch's Ordeal

Poor Job! None the less to be commiserated with whether his afflictions were malevolent visitations or psychosomatic manifestations of utter despair!

A catalogue of his woes is horrendous—not so much in severity as in obduracy. The milieu for his trial was set by two personal calamities: first, his oxen, asses and camels were caused to be stolen (the word "caused" is here used advisedly); and second, his servants and sons were killed off. At this nadir of destitution and bereavement Job's harrowing physical and psychical ordeal began.

First came boils! One boil would be bad enough, but Job was literally covered "from the sole of his foot unto his crown." With no doctor at hand, he dealt with the boils himself by scraping them with a potsherd* a procedure that hardly sounds therapeutic and must have aggravated rather than alleviated the acute discomfort.

Following the boils came hallucinations: "Then a spirit passed before my face; the hair of my flesh stood up: It stood still, but I could not discern the form thereof: an image was before mine eyes."

Then insomnia and nightmares ensued: "I am full of tossings to and fro unto the dawning of the day. Then thou scarest me with dreams."

These were succeeded by more skin disorders: "My flesh is clothed with worms; my skin is broken and become loathsome."

Then, as if he had not undergone sufficient suffering and humiliation, his wounds were exacerbated and he had trouble breathing: "For he breaketh me with a tempest, and multiplieth my wounds without cause. He will not suffer me to take my breath."

Next, to add insult to injury, he developed wrinkles: "And thou hast filled me with wrinkles, which is a witness against me: and my leanness rising up in me beareth witness to my face."

A sequence of shocking assaults next descended upon him: "He hath broken me asunder: he hath also taken me by the neck, and shaken me to pieces, and set me up for his mark. He cleaveth my reins asunder, and doth not spare; he poureth out my gall upon the ground. He breaketh me with breach upon breach, he runneth upon me like a giant."

The sense of frustration, alienation and repudiation that resulted from his relentless persecution was abysmal! "But now they that are younger than I have me in derision. They abhor me, they flee far from me, and spare not to spit in my face."

But what appeared to be the proverbial "last straw" still did not end Job's appalling endurance test. He had yet to undergo one final shattering assault: "My bones are pierced in me in the night season: and my sinews take no rest. By the great force of my disease is my garment changed: it bindeth me about as the collar of my coat. He hath cast me into the mire, and I am become like dust and ashes. My bowels boiled and rested not. My skin is black upon me, and my bones are burned with heat."

Editor's Note: Diagnosis will be welcome.

Primary Malignant Lymphoma of Small Intestine

Results of Treatment

ROGER E. CUPPS, M.D.*
MALCOLM B. DOCKERTY, M.D.†
MARTIN A. ADSON, M.D.‡
Rochester, Minnesota

ALTHOUGH PRIMARY malignant tumors of the small intestine are uncommon, malignant lymphomas comprise up to 40% of such lesions.[1] In a review of the literature Cornes[2] stated that most patients with primary lymphoma involving the small intestine die within two years of the time of diagnosis or the beginning of treatment. Usher and Dixon's[3] statistics agree in that they had no survivors beyond two years in their 19 cases of jejunal and ileal lymphoma, the average survival being 5.8 months from the time of operation. Warren and Littlefield[4] reported the cases of two patients with duodenal lymphomas who underwent gastroenterostomy and postoperative irradiation and survived five and seven years, respectively. For some unknown reason, long survivals, irrespective of the degree of involvement or type of treatment, can be expected in 2 to 3% of all cases.[5]

Marcuse and Stout[6] reported 20 five-year survivors (13.3%) among 150 patients with lymphoma of the small bowel treated by diverse means. "They were unable to determine any correlation between the clinical and pathologic aspects and the final outcome. Some patients with advanced lesions recovered, while others with early lesions suffered rapid progression of the disease despite radical therapy. The presence of involved nodes did not always preclude a successful outcome. . . ."[6]

Stout[7] considered two criteria useful in predicting survival: the cell type and the patient's age at onset of disease, the prognosis for five-year survival being better if the onset occurred after 40 years of age. (He had no 10-year survivors among the patients whose disease began in the first three decades of life.) With respect to cell type, most investigators agreed with his contention.

It is not possible on the basis of histologic type to predict the tumor's propensity to spread. However, certain generalizations based on statistics have been made, including the one that giant follicular lymphoma tends to remain localized for many years. Stout[7] reported an augmented survival of 12% for his patients with gastrointestinal lymphomas of this type. Reticulum cell sarcoma, Hodgkin's sarcoma, and lymphoblastic lymphoma, by contrast, usually spread fairly rapidly.[2] Stobbe and coworkers[8] reported a much worse outlook for patients with reticulum cell sarcoma than for lymphoblastic lymphoma and Hodgkin's disease of the stomach.

‡Mayo Clinic and Mayo Foundation: Section of Surgery.

Concerning treatment, a program combining surgical resection of the involved intestinal segment with postoperative irradiation has offered the best prognosis in cases of localized lymphoma. However, long-term survivors have been reported after the use of either modality alone, as has been the case with occasional spontaneous regression, without therapy, of histologically verified lesions.

Present Study

The cases of 44 patients with primary malignant lymphoma of the small intestine who were seen at the Mayo Clinic during the 12-year period from January 1, 1951, to December 31, 1962, were reviewed, and surgical specimens, when available, were examined. If doubt existed concerning the primary site of the disease process in the small intestine, the case was eliminated from this study. Survival data were calculated to December 1, 1968.

Microscopic sections made in each case were reviewed by one surgical pathologist to ensure uniformity in the histologic classification.

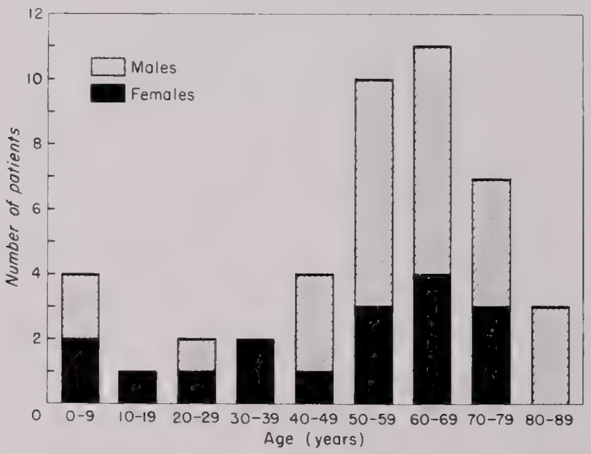

Fig. 1—Age distribution of the 44 patients at time of diagnosis.

Available roentgenograms were reviewed in conjunction with the specimens and the original surgical reports in an attempt to correlate distinctive anatomic and roentgenographic findings. No roentgenographic criteria diagnostic of lymphoma primary in the small intestine were discovered. On the contrary, the characteristic roentgenologic appearances previously ascribed to other diseases of the small bowel, both neoplastic and non-neoplastic, were demonstrated in cases of lymphoma verified by tissue examination.

Clinical Aspects

The group under study included 27 males and 17 females, forming a ratio of males:females of 1.6. The youngest patient was two years old, the oldest, 88. Figure 1 shows the age distribution by sex of the 44 patients at the time of diagnosis.

Clinical symptoms and signs were not diagnostic. Predominant presenting symptoms were abdominal pain and loss of weight. An increase in the amount of weight lost did not correlate directly with increased duration of symptoms. A palpable abdominal mass was the most frequent sign found on physical examination. Other than elevation of the sedimentation rate, results of other laboratory examinations were not contributory.

Treatment

All patients underwent surgical exploration (Table 1). Resection was carried out in 38 and biopsy with or without some bypass procedure in six. The surgical specimens were reviewed, and the length of the lesion was noted and classified into one of three groups according to Table 2. Seven patients had resection alone as the definitive treatment, whereas 31 had roentgen therapy after operation. In six of the 44 patients, the disease process was too extensive for resection. Biopsy with subsequent enterostomy, bypassing the lesion, was performed on four patients, each of whom received roentgen therapy in the postoperative period. One patient had biopsy alone followed by irradiation. One patient died during the postoperative period after biopsy and enterostomy and, therefore, did not receive roentgen therapy. In all, five patients died within one month after operation.

Pathologic Features

Classification

Dockerty's modification of Dukes' classification was applied to the tumors (Figure 2). In this classification, Type-A lesions involve only the mucosal layer of the bowel. None of the lymphomas in the present group were so limited. Sixteen lesions were classified as Type B: that is, deep mural invasion existed and occasionally extended to the peritoneum. Metastasis to regional nodes, Type C, was demonstrated in 26 cases. The latter group, comprising 62%, included the six cases of extension of tumor beyond the small bowel in which biopsy alone was performed. Insufficient information existed for classification of the remaining two of the 44 cases.

Gross Aspects

Most of the lesions were ulcerating, with the larger growths being annular. Almost a third of them were perforating. In 12 instances a peculiar appearance presented in the form of a cylindrical or aneurysmal dilatation of the bowel over the zone of lymphomatous involvement.

Microscopic Features

After review of the microscopic sections of the specimens, 20 lesions were classified as reticulum cell sarcoma, seven as lesions typical of Hodgkin's disease, eight as lymphoblastic

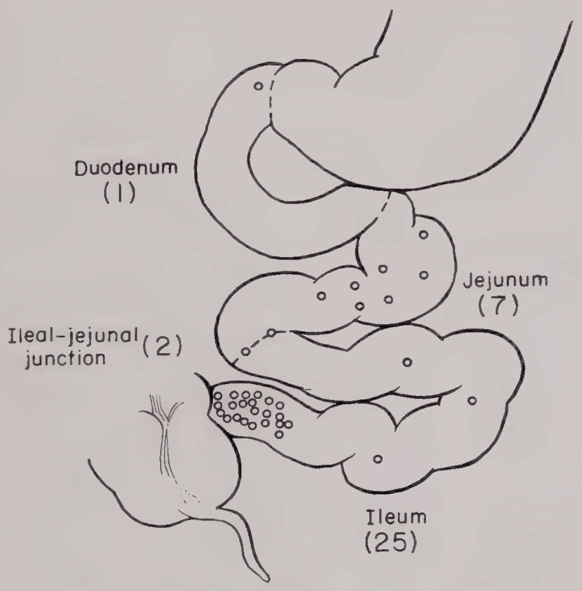

Fig. 3. Primary sites of 35 solitary lesions.

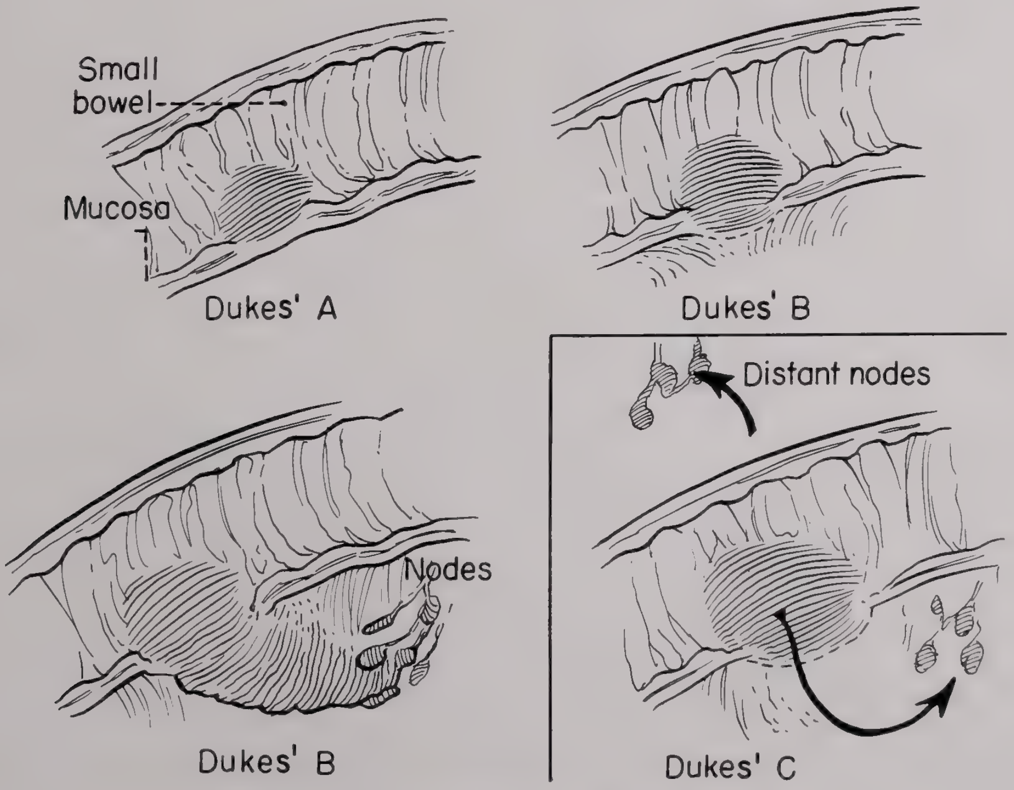

Fig. 2—Dockerty's modification of Duke's classification.

lymphoma, six as lymphocytic lymphoma, and three as giant follicular lymphoma. In 35* of the 44 patients involvement was unicentric, with 25 having tumors primary in the ileum. Two patients had lesions involving the small bowel at the ileo-jejunal junction, seven had primary jejunal lymphoma, and one patient had primary duodenal lymphoma (Figure 3).

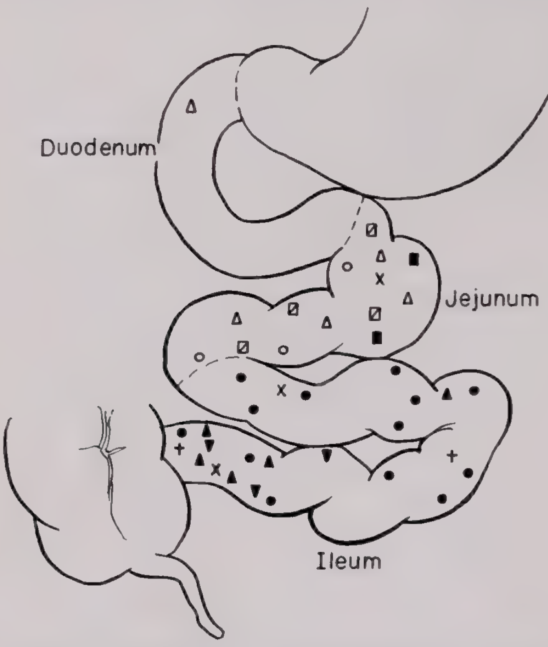

Fig. 4—Primary sites of multiple lesions in nine patients.

The remaining nine (20%) of the 44 patients had multiple sites of involvement within the small bowel. The jejunum alone was multicentrically involved in three patients and the ileum alone in four. The jejunum and ileum were both involved in one patient. Another patient had a solitary duodenal lesion with four lesions in the jejunum (Figure 4).

No relationship was found between cell type and location of the lesion in the small bowel, or between cell type and involvement, that is, whether sites were solitary or multiple.

Results

All of the 44 patients were eligible for five-year follow-up studies (Table 1). Fourteen (32%) survived five years or more. If the five patients who died during the immediate postoperative period had been excluded, the five-year survival rate would have been 36%. The five-year survival for the 31 patients who had both resection and irradiation was 45%.

Survival

Five-year survival according to treatment is listed in Table 1. The location of the primary lesion within the small bowel did not appear to affect survival (Figures 5 and 6), nor was survival statistically related to the sex of the patient (Figure 7). As would be expected, those with less extensive lesions, that is, lesions classified as Dukes' Type B, had a better chance of survival (50%) (Table 3) than those with

Dukes' Type C lesions.

As far as Stout's[7] contention that cell type has a bearing on survival, five of 20 patients with reticulum cell sarcoma were living five years after operation; three of six patients with lymphocytic lymphoma survived a similar period (Table 4).

Lymphoblastic lymphoma	2	6
Lymphocytic lymphoma	3	3
Hodgkin's disease	2	5
Giant follicular lymphoma	2	1
Total	14	30

Only one of seven patients with disease presenting in the first three decades of life survived five years or more (Figure 7).

The surgeon's notes were interesting. Of the 14 survivors, seven were believed to have had all of the grossly involved portion of the small intestine surgically removed, while of the 30 patients who died within five years, only three were considered to have had all diseased intestine surgically resected.

The reasons that seven patients did not receive roentgen therapy after operation were as follows: Four died before such therapy could be started (three within the 30 days immediately after operation and another six weeks after operation). One patient, 79 years of age with a fractured hip, was considered too elderly to undergo the rigors of roentgen therapy. Another elderly man had had such extensive resection and had such persistent diarrhea that he was not considered a satisfactory candidate for roentgen therapy. In one case roentgen therapy was denied because of the surgeon's impression that the patient had no residual tumor.

Dosimetry

Records of roentgen therapy received by these patients were reviewed and dosimetry* was approximated by using the Alderson phantom.

---

*See Test Your Word Score Page 1921.

In the early part of this study, supervoltage equipment was not available, while in the group treated from the late 1950s onward, cobalt teletherapy was often employed. In the patients who survived five years, selected treatment plans were re-created, using the Alderson phantom. Field sizes recorded in the patient's record of roentgen therapy and treatment factors were duplicated.

Roentgen therapy was begun two weeks to one month after operation, depending on the patient's clinical condition. Generous fields were employed in most instances with opposing portals used to irradiate the abdomen from the dome of the diaphragm to the inferior margin of the symphysis pubis. Prior to initiating therapy, careful physical examination did not demonstrate peripheral adenopathy. Neither the liver nor the spleen could be palpated in any instance. Tests of liver function performed prior to operation did not reveal any abnormality. Roentgenograms of the chest showed no evidence of mediastinal adenopathy or parenchymal lesions.

In every case in which a gross residual tumor remained after operation and in which five-year survival was achieved, the patient had received a minimal dose of 2,000 rads at the level of the midplane of the abdomen. Fractionation varied from 16 to 20 days of treatment, as indicated in the following report.

Case Report

History

In December 1955 a 71-year-old man was hospitalized because of vomiting of two weeks' duration. In 1953 he had experienced a sudden hemorrhage from the rectum. A burning sensation in the abdomen, noted the night before, was followed by passage of bright red blood at 5 a.m. At that time transfusion of blood was required. On November 28, 1954, he had a sudden single episode of severe hematemesis which ceased after transfusion of blood and emergency treatment including gelfoam liquid. The last hemorrhage from the rectum took place on May 5, 1955, at which time the patient stated that he had had an attack of influenza approximately one week earlier. He took a laxative, after which he had diarrhea soon followed by bleeding. On May 13, 1955, he received a blood transfusion. In June 1955 the patient was examined at the Mayo Clinic. At that time no cause for his gastrointestinal symptoms could be found.

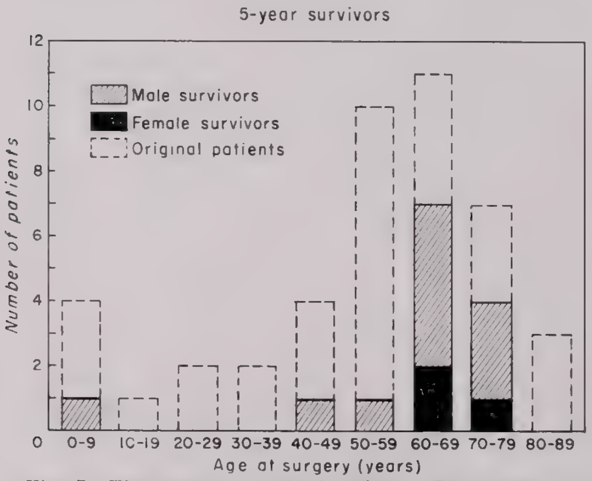

Fig. 7—Five-year survival of patients. Distribution by age at operation and by sex.

Two weeks prior to his hospitalization in December 1955 the patient began to vomit after eating. Vomiting relieved the pressure and made him feel better. In the morning he felt well; however, as the day progressed he noted increasing discomfort in the upper part of the abdomen. He felt that his food was being retained too long and stated that "when the next meal comes it accumulates." During the night, when he did not eat, the abdominal discomfort decreased. Bowel habits continued to be normal until two days prior to his hospitalization. At that time he stopped eating solid food. His appetite, however, was good, but he had lost 24 pounds during the previous six months.

The patient was born and raised in Russia and came to the United States at the age of 21 years. In 1918 he had had a "severe" attack of influenza. In 1940 he had undergone a submucous resection and adenoidectomy elsewhere. In 1951 he noticed a left inguinal hernia but did not seek medical advice.

Laboratory Findings

Results of laboratory studies on December 2, 1955, were as follows: hemoglobin 13.8 gm with a leukocyte count of 6,600 and a differential of lymphocytes 21, monocytes 4, neutrophils (segmented 56, band form 18), and eosinophils 1. The erythrocyte count was 4,310,000. The blood urea was 54 mg/100 ml. Sodium was 137, potassium 4.0, chlorides 98, and Co_2 21 mEq/liter.

On December 6, 1955, after fluoroscopic examination of the upper gastrointestinal tract, the roentgenologist reported that loops of jejunum in the left upper quadrant were bound together and distended. The loops were difficult to examine, but he suspected that there was an enteroenteric fistula which was probably related to a malignant lesion in the jejunum.

Treatment

On December 10, 1955, the patient underwent operation through a primary left rectus incision. Above the stomach, apparently in the celiac axis region, were multiple enlarged, firm lymph nodes which could not be exposed. The proximal jejunum was dilated and a huge mass in the upper jejunum was surrounded by omentum and fat tags. Part of the omentum was removed. The fat tags were excised, which mobilized the lesion well. The mesentery contained many large nodes. As much as possible of the mesentery was removed without sacrificing the superior mesenteric artery, but many enlarged nodes remained. Wide resection was accomplished. A fistula between loops of jejunum was exactly as described by the roentgenologist. The entire mass came out cleanly and end-to-end jejunojejunostomy was established. The defect in the mesentery was closed by suture. No other lesions could be demonstrated.

The pathologist reported an annular, ulcerative, perforating, necrotic, obstructing reticulum cell sarcoma measuring 14 by 7 by 5 cm. It had produced a fistula into the jejunum 10 cm distal to the lower level of the primary tumor. The lymph nodes were inflamed. The lesion was classified Dukes' Type B.

On January 9, 1956, the patient began roentgen therapy. A cobalt-60 teletherapy unit was employed with a source-skin distance of 80 cm. Treatments were directed through opposing anterior and posterior portals measuring 16 by 15 cm and over 18 treatments 2,000 rads were delivered at the level of the midplane of the abdomen.

The patient was last examined at the Mayo Clinic on November 27, 1957, at which time there was no evidence of recurrent sarcoma. In a follow-up letter on October 26, 1966, the patient stated that he had high blood pressure but no known recurrence of his tumor.

Summary

At the Mayo Clinic, 44 cases of primary malignant lymphoma of the small intestine were encountered during the 12-year period, January 1, 1951, to December 31, 1962. Cases were reviewed and surgical specimens, when available, were examined. If doubt existed concerning the primary site of the disease process in the small intestine, the case was eliminated from the study. Survival data were calculated to December 1, 1968. All patients had undergone surgical exploration. Records of roentgen therapy of these patients were reviewed and dosimetry was approximated by measurements using the Alderson phantom. The current treatment of choice for primary malignant lymphoma in the small bowel is surgical resection followed by roentgen therapy. No five-year survivors in this group were obtained by any other method of treatment.

Echelle de six Toises

Broutins plan and elevation of a wing of the hospital, dated June 6, 1737. reference: Archives Nationales, section Outre-Mer, Atlas Moreau de Saint Mery, No. 28.

The first hospital in the Mississippi Valley was the military hospital built at the newly-founded French colonial city of New Orleans. Completed in 1722, it was a wood frame building, fifty by twenty feet, raised a foot or two off the ground, and located on the quay facing the river at the corner of the present Ursuline Street.

The tiny facility was designed to accommodate sixty to eighty patients. Situation of the new city in the midst of fever-ridden swamps, however, soon resulted in an influx of the sick which overflowed the hospital and forced the use of an uncompleted warehouse for convalescents.

By 1726, a companion building the same size as the first had been completed, allowing separation of patients with infectious diseases from the others. The hospital grounds were surrounded by palisades enclosing gardens to provide fresh vegetables for the sick. In the same year, the Ursuline nuns of Rouen in France agreed to undertake the task of caring for the patients of the New Orleans hospital.

A convent for the Ursulines was begun about a block downstream from the hospital. The hospital buildings were deteriorating so rapidly that the colonists decided to relocate the hospital adjacent to the new convent on what came to be called Hospital Street, now Governor Nicholls Street. In August, 1732, one of the old hospital buildings was destroyed by a hurricane, crushing 26 beds and accompanying furniture. Fortunately, the patients had been removed before the structure collapsed.

(Continued to page 1921.)

Regional Enteritis

Early Diagnosis

SEWELL S. GORDON, M.D.*
St. Louis Park, Minnesota

My purpose in writing on the subject of regional enteritis is to emphasize those features which might enable us to make the diagnosis much earlier in the course of its clinical evolution. These features include both clinical and radiological considerations.

Early Clinical Considerations

Perhaps ten percent of cases appear as acute abdominal emergencies. If there is no clinical clue that one might be dealing with a more chronic disease, the patient is often operated on with a tentative diagnosis of appendicitis. After seeing the tremendously thickened discolored ileum, the surgeon will usually recognize his error, realizing that many of these lesions, especially in children, regress spontaneously. Accordingly, most surgeons will close the abdomen without bowel resection or anastomosis. Even in the cases where the diagnosis is suspected at surgical exploration, the surgeon is well advised to confirm the diagnosis and determine the extent of the disease roentgenographically. The clinician must order a barium enema and indicate his suspicions in order that the radiologist can carry out the proper technique to make the diagnosis on the basis of these studies. These two requirements seem simple enough but, due to the failure of one or the other, the diagnosis is frequently delayed for months and years. In reviewing the charts of many of these patients, it is remarkable how frequently the patient has carried a diagnosis of psychosomatic disease until a diagnosis of regional enteritis was eventually established.

If one waits for the classical clinical history of fever of undetermined origin, intermittent abdominal cramps and diarrhea, extensive weight loss, abdominal gurgling, and all of the other signs of debilitating disease before thinking of regional enteritis, he will almost always diagnose it in an advanced stage. In the modern practice of medicine, this diagnosis should be made whenever there is a suspicion of disease of the gastrointestinal tract. Obviously, anyone with an externally draining fistula or pararectal abscess, in view of the frequent association with ileitis or ulcerative colitis, should be studied.

---

*Department of Radiology, St. Louis Park Medical Center, St. Louis Park, Minnesota.

Roentgen Diagnosis

Once the roentgen examinations are ordered the diagnostic burden is on the radiologist. This observer has been impressed by the number of these patients who have had what was called a normal barium enema previously. Most of these people did not have a small bowel study. Roentgenograms from a few of these outside studies were reviewed; most of them were non-diagnostic technically.

Why does a radiologist miss the diagnosis of regional enteritis? It cannot be that he has not heard of the "string sign" and the "skip areas." The radiologist must establish a routine of seeing the terminal ileum in every examination in which it is possible to fill it.

Adequate Filling

It is distinctly unusual not to be able to fill the ileum when the ileocecal valve is infiltrated by the inflammatory process of regional enteritis. When the ileum is filled in good volume, sharp spot films should be made of the area. If there is the slightest suspicion of mucosal irregularity on the enema study, a small bowel should be done with 24 ounces of a non-flocculating barium. In this way the entire small bowel can be filled in continuity, and thus the study proceeds much more quickly. When the entire small bowel is filled, an abnormally thick-walled loop is easily recognized by virtue of displacement of adjacent loops of bowel. With the non-flocculating barium the mucosal pattern is exquisitely outlined.

Serial Roentgenograms

A series of roentgenograms is made beginning at five minutes after completion of the upper gastrointestinal study. From then on the timing is based on the rate of progress. It is important to see all areas of the small bowel more than once. Transitory configurations often stimulate pathology, but if the pattern is truly abnormal, it will be persistent. The terminal ileum should be seen clearly emptying into the ascending colon on more than one film. This is by far the most important portion of the small bowel since it is the most frequently involved in disease processes. This includes adhesions, periappendiceal abscesses, lymphosarcoma, and carcinoma of the cecum, in addition to regional enteritis.

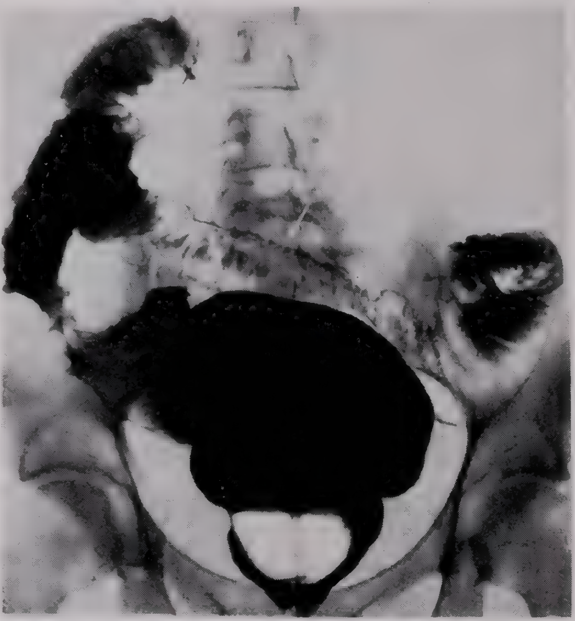

Fig. 1A—Patient has had a previous colectomy with ileosigmoid colostomy. There is narrowing at the anastomosis (single arrow) which overlies the wing of the right ileum. The ileum above the anastomosis is slightly dilated. Its mucosal margin is etched (double arrow). There is diffuse ulceration of the distal 25 centimeters of the ileum.

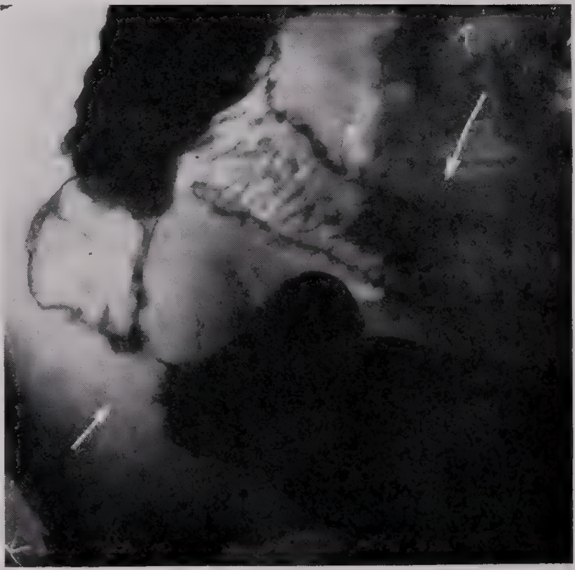

Fig. 1B—Spot film of the anastomotic (single arrow) area demonstrates more effectively the diffuse shaggy ulceration (double arrow) involving all of the visualized portion of the ileum to the level of the anastomosis. Changes are consistent with a diagnosis of regional enteritis.

Distortion of Mucosal Pattern

There is primarily one finding we must seek out. This is simply *any* constant distortion of the mucosal pattern. If all we see is a faintly fuzzy small bowel margin several centimeters in length on two or more films, we may be suspicious. If there is the slightest evidence of thickening of bowel wall along with it, we have enough evidence to make the diagnosis; any more advanced changes make the diagnosis more certain. Even in the early stages, the involved loops maintain a fixed position that is very helpful in ruling out a transient mucosal distortion.

Case Presentations

Case 1

This 37-year-old white female presented in 1960 with many complaints. Her appetite was poor and she stated that she might have lost some weight. She complained also of mild abdominal gurgling. In retrospect, it was clear that she had had symptoms for at least three years prior to her workup in 1960, which was done because of the presence of anemia. She had had a colectomy for chronic ulcerative colitis in 1951, when the terminal ileum was anastomosed to the sigmoid. Subsequently she had had no gastrointestinal symptoms until 1957 when her present gastrointestinal symptoms began. A barium enema, upper GI study, x-rays, and sigmoidoscopy at a University center revealed no abnormality. Because of this negative result no further definitive examination was made until 1960 when a sigmoidoscopy examination was again done. Diseased bowel was seen proximal to the anastomosis. A barium enema showed evidence of a previous colectomy with ileosigmoidostomy (Figure 1). The stoma was appreciably narrowed. The more proximal ileum was moderately dilated. There were approximately 25 centimeters of terminal ileum involved with a diffuse ulcerative process.

Comment

In this patient there was a three-year delay in recognition of acute disease despite the fact that she had had a previous colectomy for chronic ulcerative colitis. Pertinent also is the fact that she had had a negative gastrointestinal workup in 1957, but without a small bowel study.

Case 2

This 27-year-old female, after delivery of a child in 1953, complained of recurrent diarrhea with three to five bowel movements daily and gave a history of having had an episode of diarrhea lasting several months in 1951, associated with gaseousness and gurgling abdominal sounds. On examination active bowel sounds were noted. An initial barium enema, at this clinic in 1953 (Figure 2-A, B), was called normal despite the large

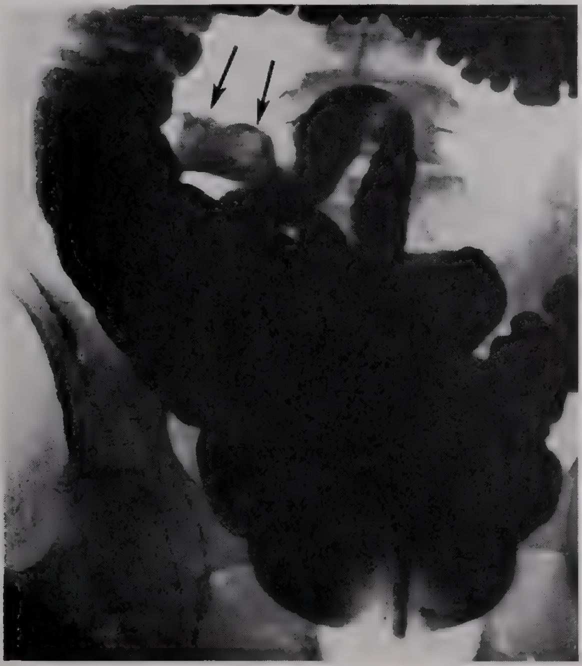

Fig. 2A—Filled film on barium enema dated March 21, 1953. There is mottled radiolucency in the right colon representing retained fecal material. Filling defects (arrows) in the ileum were assumed to be on the same basis. Note irregular and fuzzy contour of the terminal ileum. There is separation of ileal loops.

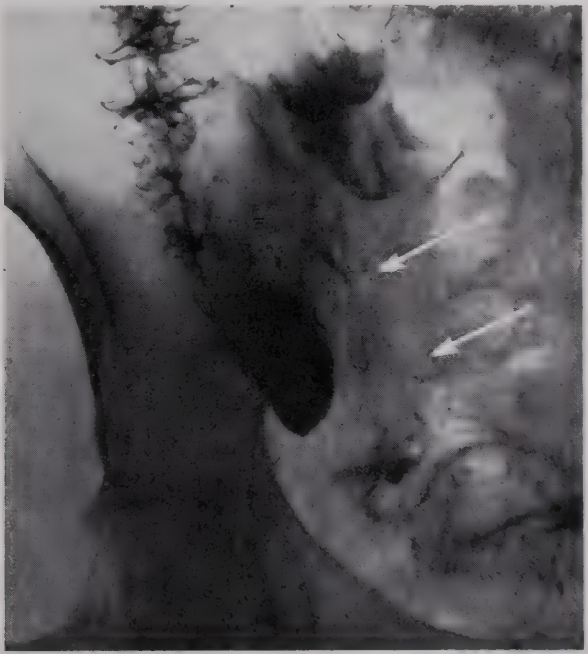

Fig. 2B—Postevacuation barium enema March 21, 1953. The evacuated ileum (arrows) does not have a normal feathery mucosal pattern. The ileum lying within the right side of the pelvis has a denuded appearance highly suggestive of regional ileitis. The diagnosis should have been made at this time.

amount of retained fecal material within its ascending segment and also in the terminal ileum. Serration of its wall was regarded as of no significance. No small bowel study was ordered.

In 1963, ten years after the original one, the patient had a second barium enema here which showed extensive regional enteritis (Figures 2-C, D).

Comment

It is clear that the serration of the ileum seen on the initial study was a significant finding. We can learn from this case not to dismiss minimal mucosal findings. A small bowel study should have been done in 1953. A barium enema should have been repeated, with an attempt at better bowel preparation.

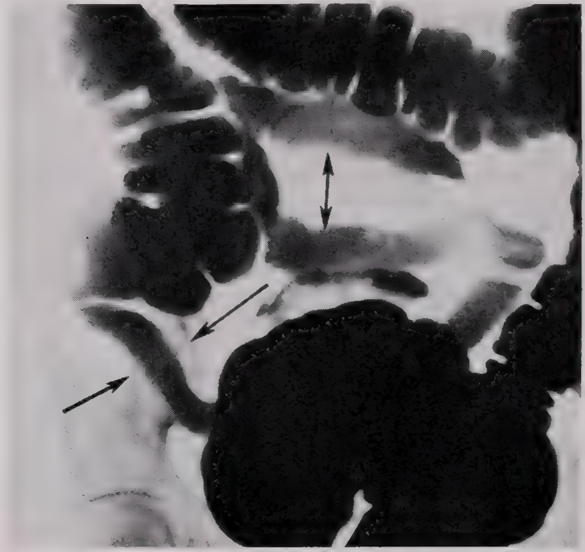

Fig. 2C—Followup barium enema March 16, 1963. This study, including pre-and post-evacuation roentgenograms, shows the extensive changes of regional enteritis. There has been progression since earlier study of 1953 (arrows).

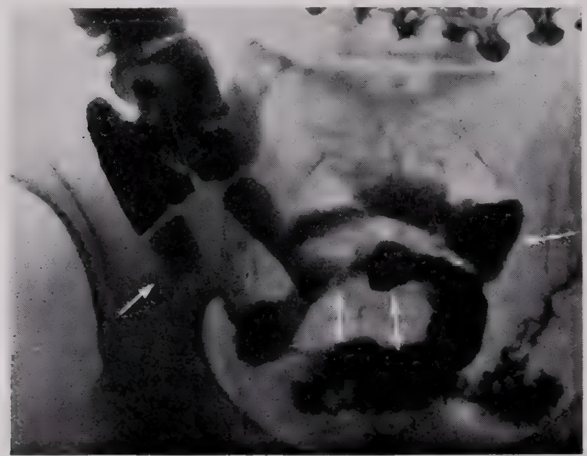

Fig. 2D—Extensive changes of regional enteritis.

Case 3

This 34-year-old white male was first seen on November 15, 1958, and was treated initially for functional bowel complaints including intermittent diarrhea. He complained also of intermittent distress in the right groin area. He was checked for a hernia but none was found. He returned in March of 1959, at which time a partial workup was normal. In September of 1959 he complained of recurrent pain in the right lower quadrant and groin. In March of 1963 he returned with recent onset of diarrhea. At this time both the barium enema and small bowel studies showed typical but mild changes of regional enteritis (Figure 3).

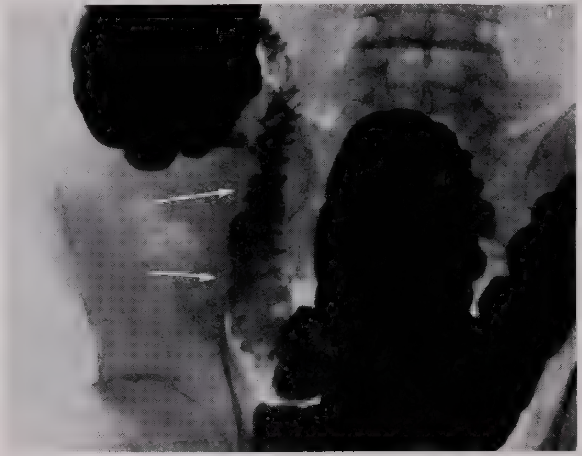

Fig. 3A—Barium enema with filling of terminal ileum. There are numerous "cobblestone" filling defects (arrows) within the terminal ileum. There is slight marginal irregularity of the ileum. On the basis of this film alone, it would be difficult to be certain that we are dealing with regional enteritis. A similar appearance could be given in the presence of prominent lymphoid follicles.

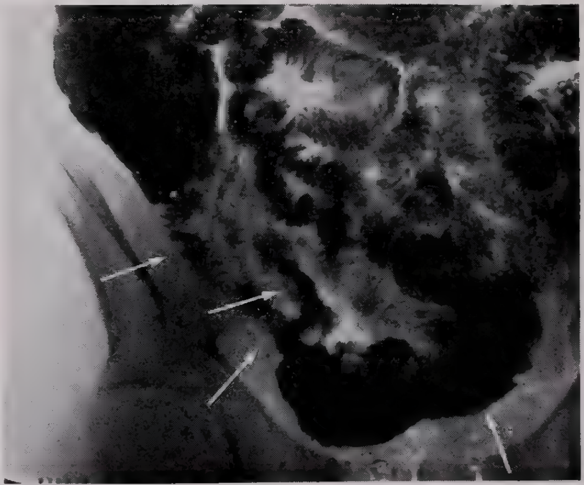

Fig. 3B—Roentgenograms of a small bowel series done three days after the barium enema. We see numerous abnormal small bowel loops (arrows). There is separation of the loops due to the thickened walls and pointing of circular small bowel folds with irregularity of the pattern of the folds. These are minor but constant changes and clearly indicate the presence of regional enteritis.

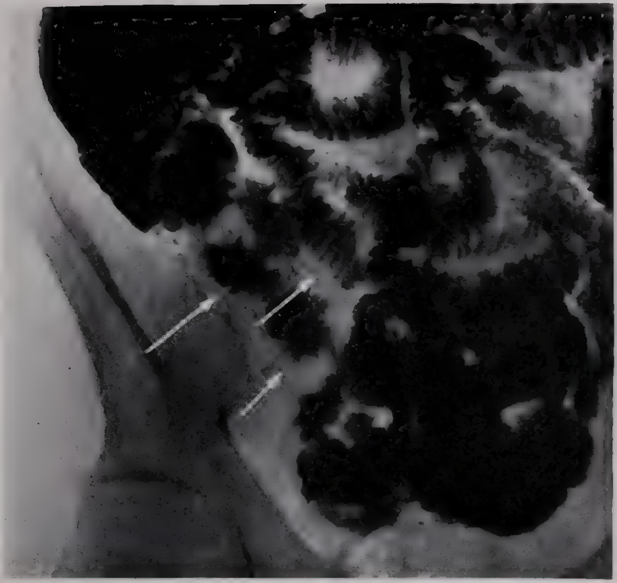

Fig. 3C—Roentgenogram of small bowel series done three days after the barium enema.

Comment

This man was treated on an assumption of functional bowel complaints. He went almost five years before having either a barium enema or a small bowel study.

Case 4

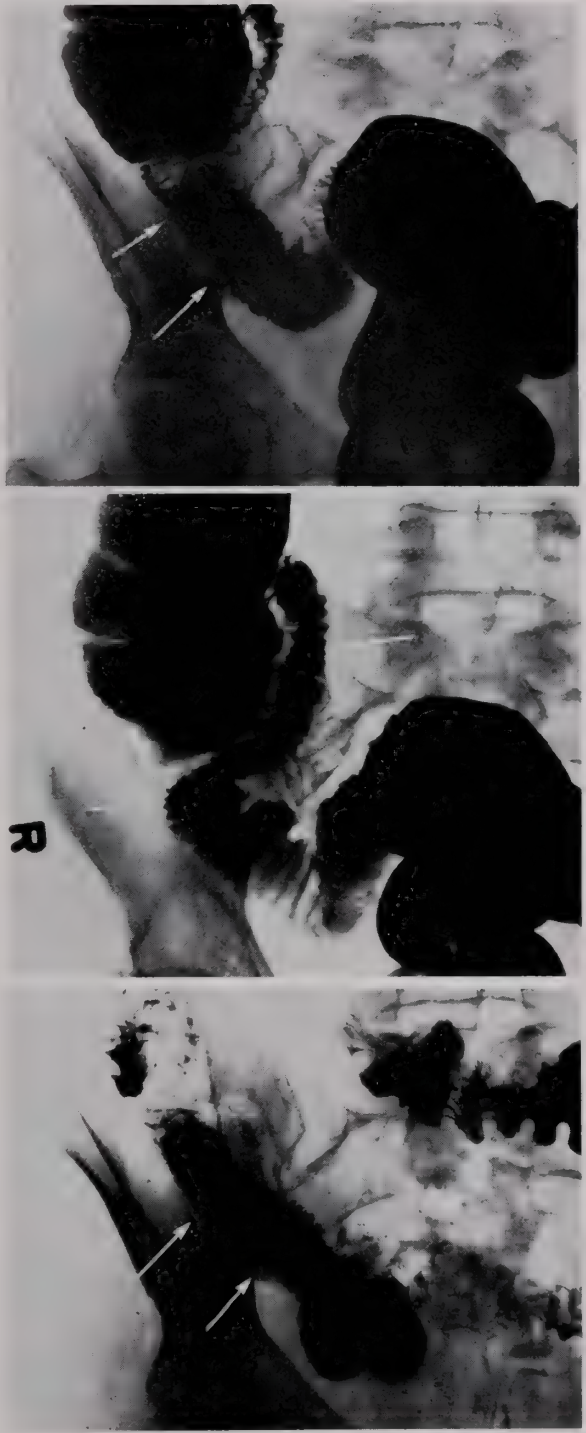
This 33-year-old female complained of chronic abdominal distress and indigestion in January 1957. She had belching relieved by Alka-seltzer. There was mild abdominal tenderness localized directly over the umbilicus. An upper gastrointestinal x-ray was called normal. She returned in March of 1958 because of chronic intermittent bowel complaints manifested by three to four bowel movements daily and a feeling of gaseousness. On physical examination her abdomen was negative. The tentative diagnosis was chronic irritable bowel syndrome. She was seen again in April and May for persisting gastrointestinal symptoms associated with diarrhea, cramps and gurgling. Physical examination revealed hyperactive bowel sounds. A barium enema, done on May 20, 1958, showed minimal changes of terminal ileitis (Figure 4).

Comment

There was a delay from onset of symptoms to definitive gastrointestinal tract workup of one and a half years. Again noted is the functional diagnosis of "chronic irritable bowel syndrome."

Case 5

This 38-year-old male appeared in 1965 complaining of severe diarrhea, with five to six bowel movements daily which were relieved by large doses of paregoric.



Figures 4A (top), B (middle), and C (bottom)—Barium enema. Prone, supine, and postevacuation roentgenograms of the right lower quadrant demonstrate a fixed position of the distal ileum relative to the colon and to the surrounding bony structures. The margin of the terminal ileum is somewhat fuzzy (arrows). There is a slight loss in the normal orderly pattern of the circular folds. From the standpoint of the roentgen diagnosis, the findings are considered highly suspicious of regional enteritis. The diagnosis is, however, not unequivocal. A small bowel study was suggested, but the patient was lost to followup.

He was hospitalized one month later for this same complaint. A barium enema and upper gastrointestinal and small bowel x-ray studies were called normal. The patient was told that his problems were probably psychiatric in nature. Despite this he continued to have diarrhea. While on a business trip in August 1965 he noted abdominal pain and distention. Admitted to a hospital he was given intravenous fluids as well as antibiotics. Apparently at that time he had had no bowel movement as his symptoms were relieved when his bowel movements began, and he was told that he had had an episode of acute bowel obstruction. When he returned to this city he again began to have intermittent bowel complaints, and on this occasion he had another gastrointestinal workup. The barium enema showed regional ileitis involving the terminal 20 centimeters of ileum. This was confirmed by a small bowel study (Figure 5). The patient has responded well to therapy with corticosteroids, antibiotics, and a general antidiarrhea regime. However, he flares up frequently when weaned off drugs or with any dietary indiscretion.

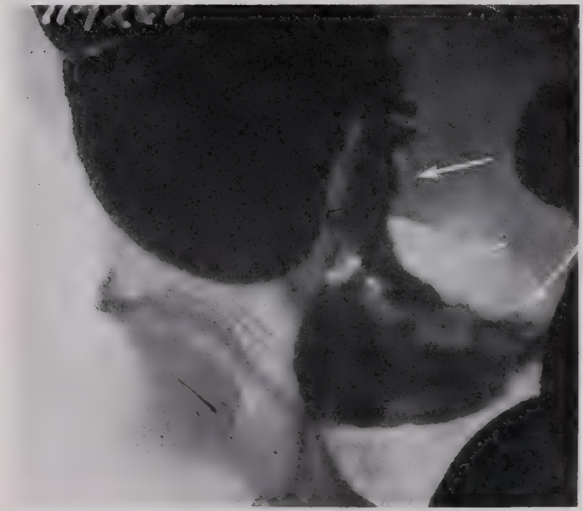


Fig. 5A—Spot films of the terminal ileum from a barium enema study. There is loss of mucous membrane pattern (arrows) and irregularity of the lumen of the ileum. There are filling defects and presumably ulcerations of the ileum.

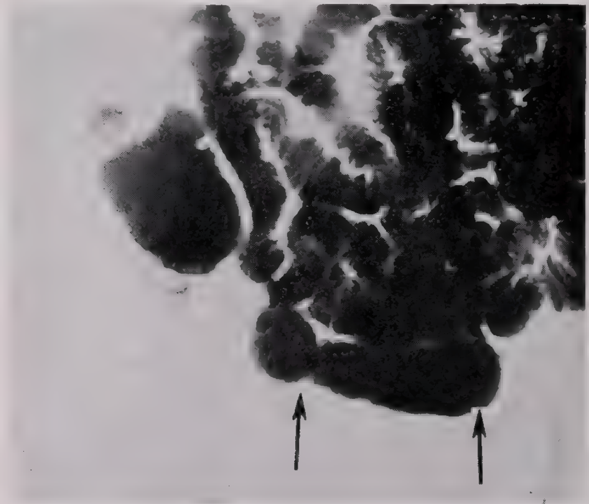

Fig. 5C—Small bowel study does not demonstrate the area of involvement very effectively. The very lowest small bowel loop demonstrated is, however, clearly abnormal (arrows).

Comment

This patient had severe complaints. He was clearly a tense and jittery individual, and this was undoubtedly aggravated by the fact that no organic disease could be found to explain his symptoms. He improved considerably with the simple knowledge that he had a real disease of his bowel.

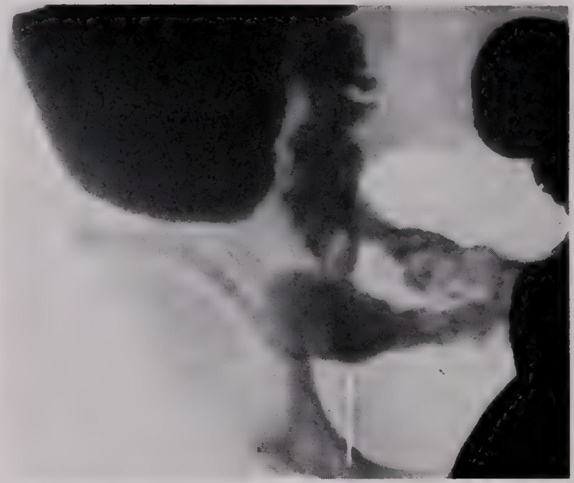

Fig. 5B—Spot film of the terminal ileum from a barium enema study.

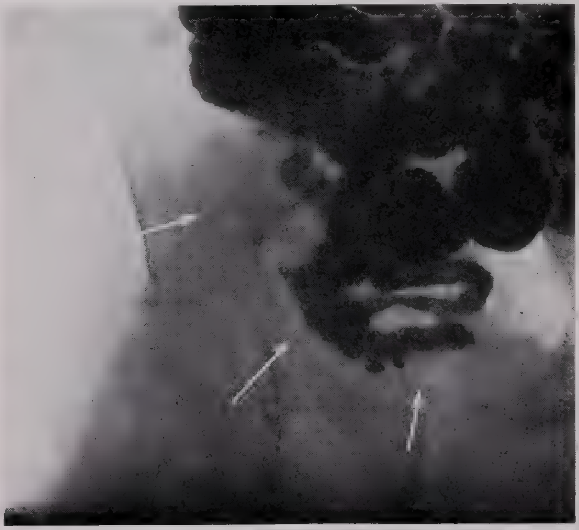

Fig. 6A—Roentgenograms from small bowel study show a constant pattern of denudation of mucosa, irregularity of lumen, fixation of position, and separation of adjacent loops (arrows). Findings are characteristic of regional enteritis.

Case 6

This 23-year-old white male was recognized as being anemic when he went to the blood bank to donate blood. His hemoglobin at this time was 10.4 grams. He stated that he was feeling fine. He was admitted to the hospital for a workup to determine the cause of his iron-deficiency anemia. Though a barium enema and upper gastrointestinal study were called normal, a subsequent small bowel study (Figure 6) showed involvement of the descending duodenum with narrowing and some loss of mucosal pattern in the mid-ileum characteristic of regional enteritis. In retrospect the patient recalled that he had had some diarrhea and cramps. About four months after the diagnosis was made he was having loose bowel movements and was then put on steroid therapy with an apparent good bowel response. This patient has left the city and we have no report relative to the response of his anemia.

Comment

The referring internist had elicited no history of gastrointestinal disturbance; hence we can only presume that the regional enteritis was the cause of his anemia. This case stresses the importance of seeing the terminal ileum and having good spot films of it.

Conclusion

A high index of suspicion by both the clinician and the radiologist can lead to the earlier diagnosis of regional enteritis.

Acknowledgment

Many thanks are due to Miss Monica Doran, Chief Technician, and other technicians at the St. Louis Park Medical Center for their help in assembling these cases.

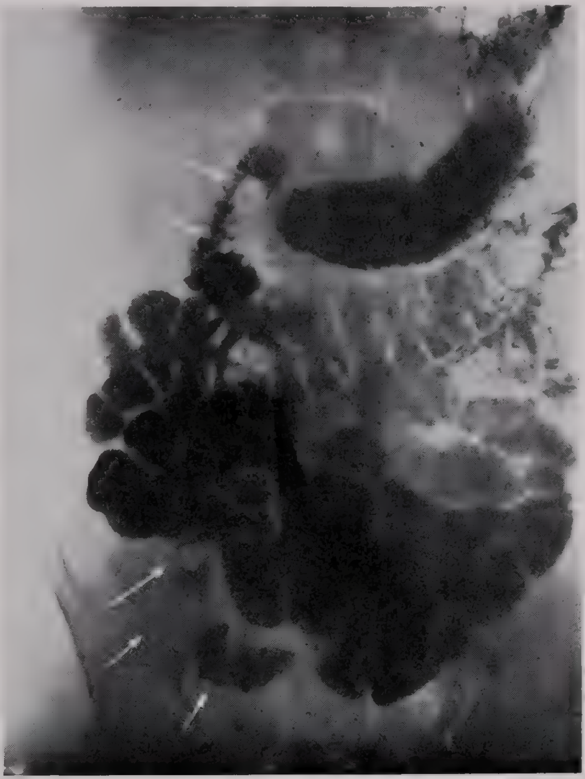

Fig. 6B—Another roentgenogram of same case. There are minor changes in the second and third portions of the duodenum seen in B (arrows) only.

The Golden Age

In the second half of the nineteenth century, the world of medicine at last abandoned the systems and dogmas that for centuries had done violence to the sick body. . . . At the bedside, the physician put aside his gold-headed can and approached the patient as a wise friend talking in simple language and offering rational therapies. His blend of science and practical experience inspired confidence, and his concern for the patient's comfort of body and mind won the patient's affection. Thus began the golden age of the general practitioner.

Charles Darwin enjoyed the care of such a family physician in Sir Andrew Clark, who tended him in the later years of his lifelong invalidism. Sir Andrew's friendly cheerfulness buoyed the despondent naturalist through his periodic bouts with headache, indigestion, vomiting, palpitations, dizziness, insomnia, and extreme fatigue.*

Editor's Note: Anyone who would go sailing on the Albatross for a couple of years must have had a restless spirit. It sounds to me like he was extremely functional and somewhat of a perfectionist. No doubt with this type of a disposition and temperament he found many of the everyday activities distressing to his sensitive soul. Well, everybody can't be a stoic!

Even a waiter sometimes comes to him who waits.—Herbert Prochnow

Morquio's Syndrome

Morquio's syndrome is an hereditary dystrophy of cartilage and bone that results in dwarfism and generalized skeletal deformity. Morquio and Brailsford, independently, in 1929 first described the essential features. The syndrome is transmitted as a recessive character; familial influences are common. There is a slight predilection for the male. The incidence is relatively rare.

Early manifestations of the developing dwarfism become apparent between the ages of four and 10 years. The spine is the most severely affected part of the skeletal system with curvature, kyphosis, shortening, and almost constant angulation at the dorsolumbar region. Chest deformity with increased anteroposterior diameter, forward thrust of the sternum, raised clavicles, and short neck become apparent as age increases. Other features include genu valgum and large feet with varus deformities. Lax ligaments, decreased muscle tone, joint crepitation and deformity, and delayed ossification of the epiphyses are frequently present. The combined abnormalities usually result in a duck-waddling gait. Roentgenograms of the skull are normal. Intelligence is usually unimpaired.

The cause of these developmental anomalies is not known. Differential diagnosis should exclude Hurler's syndrome, which is characterized by an enlarged shoe-shaped skull, hepatosplenomegaly, mental retardation, and corneal clouding. The wedge-shaped deformities of the vertebral bodies in Leri's syndrome may resemble those of Morquio's syndrome. Bone deformities in Morquio's syndrome are progressive, and there is increasing disability until walking becomes impossible.

The Slowly Moving Finger

In general, among all groups of organisms sharing a common plan of structure, the large ones live longer than the small. Among plants, the giant sequoia tree lives longer than the daisy. Among animals, the giant sturgeon lives longer than the herring, the giant salamander lives longer than the frog, the giant alligator lives longer than the lizard, the vulture lives longer than the sparrow, and the elephant lives longer than the shrew.

Indeed, in mammals particularly, there seems to be a strong correlation between longevity and size. There are exceptions, to be sure—some startling ones. For instance, whales are extraordinarily short-lived for their size. Most cetaceans are doing very well indeed if they reach 30. This may be because life in the water, with continuous loss of heat and the never-ending necessity of swimming, shortens life.

But much more astonishing is the fact that man has a longer life than any other mammal—much longer than the elephant or even than the closely allied gorilla. When a human centenarian dies, of all the animals in the world alive on the day that he was born, the only ones that remain alive on the day of his death (as far as we know) are a few sluggish turtles, an occasional ancient vulture or sturgeon, and a number of other human centenarians. Not one non-human mammal that came into this world with him has remained. All, without exception (as far as we know), are dead.*

Past
and
Present
(1935-1968)

Harold O. Peterson, M.D.†
Minneapolis, Minnesota

As a measure of the esteem in which he was held by his fellow radiologists and in recognition of the many contributions he made to the developing field of radiology, three series of lectures have been established in memory of Russell Daniel Carman, M.D. The Minnesota Radiological Society instituted its Carman lectureship early in 1934. Later that same year, the Radiological Society of North America also initiated a Carman lecture which continued until recent years. In addition, the St. Louis Radiological Society sponsors a Carman lecture.

The roster of the 33 previous Carman lecturers to this society read like a "Who's Who" of radiology. I feel very humble indeed to be added to this great array of former lecturers, four of whom (A. B. Moore, M.D.—1934, B. R. Kirklin, M.D.—1946, C. A. Good, M.D. —1961, and L. G. Rigler, M.D.—1964) were members or former members of the society when they gave this lecture. As Dr. Good has remarked, "It is a double honor indeed to be invited to lecture to one's fellow members."

Dr. Carman was born in Iroquois, Ontario, on March 18, 1875. As a young child, he came with his mother to St. Paul where he received his grade and high school education. His premedical training was taken at the University of Minnesota, and in 1901 he received his M.D. from the Marion Sims-Beaumont Medical College of St. Louis (later merged with the St. Louis University School of Medicine). His career was from the beginning oriented toward medical aspects of the roentgen ray. There were no departments of radiology in those days, and individuals in various fields of medicine worked with this new diagnostic tool. Thus it was that Carman took post-graduate training under Dr. F. H. Baetger, Professor of Orthopedic Surgery at Johns Hopkins University and a man especially interested in the

*Carman Lecture 1968.
Presented at the Fall Meeting of the Minnesota Radiological Society, 1968.

†Professor and Retiring Head, Department of Radiology, University of Minnesota Medical School.

applications of x-ray to medicine. He returned to St. Louis in 1903 and for the next ten years practiced radiology while teaching first at St. Louis University and later at Washington University.

In 1913, Dr. Carman was invited to become the first full time director of radiology at the Mayo Clinic. For the next 13 years, until his death on June 18, 1926, he learned, mastered and taught the art and science of radiology while developing one of the largest and most outstanding departments in the world. During this period he was also at different times President of the American College of Radiology and the Radiological Society of North America and was President-Elect of the American Roentgen Ray Society when he died. I do not believe any other radiologist has held all three positions. Within three months following his death, the American Roentgen Ray Society presented a plaque in his honor which stands today in the lobby of the Mayo Clinic.

Dr. Byrl Kirklin, a student, close associate, and successor to Carman at the Mayo Clinic, gave the first Carman lecture to the Radiological Society of North America in 1934.[1] His remarks at that time, which I would like to quote, give those of us who did not know Carman some insight into what made this man such an outstanding radiologist:

> "When Carman came to Rochester in 1913, he knew relatively little about gastrointestinal radiology. When he walked out of the screen room for the last time, . . . he was undoubtedly one of the ablest radiologic diagnosticians of gastric and duodenal disease in the world. How did he acquire this knowledge and skill? Not by sparkling brillance of mind or effortless inspiration, but by hard work, well applied.
>
> Carman's mental processes were simple, direct, almost invariably accurate, and above all thorough. . . . All that Carman knew, which was much, he learned at first hand and knew beyond all shadow of doubt. He knew the morbid anatomy of gastroduodenal disease in relation to its radiologic manifestations as few other men have ever known it. His mental picture of gastric cancer, for example, was not derived merely from drawings, or from photographs or lantern slides, but from its varied radiologic images, its appearance when the abdomen was opened, its gross aspects after removal, and its histologic structure as revealed by the microscope, all of which he synthesized into a coherent and practical conception of the disease. Thus Carman not only taught by trustworthy precept, but set an example which may well be followed by all radiologic diagnosticians."

John Camp, who presented the Radiological Society of North America Carman lecture in 1949, stated:[2] "Carman was great because of his uncanny powers of observation which he applied to his work in an effort to know the truth and impart it to others. Morning after morning, year in and year out, he spent in the operating room and in the pathology laboratory correlating the findings of the fluoroscopic room and the roentgenogram. He was not satisfied to be right or wrong, he must know why."

Myelography

Although no previous Minnesota Radiological Society Carman lecturer has discussed the subject of myelography, Camp delivered the Radiological Society of North America Carman lecture in 1949 under the title "Contrast Myelography Past and Present".[2] He covered the subject extremely well. Indeed, there have been no major advances in myelography since 1950. I have chosen the same title today and hope to add some minor points from my own experience in the areas of myelographic technique and anatomy and in the myelographic diagnosis of disc disease.

Air Myelography

The history of myelography dates back to 1919, at which time Dandy predicted the usefulness of air myelography in his classical paper on encephalography.[3] The first deliberate air myelograms, however, were performed by a Swedish internist, Jacobeus, later that same year. He reported his first three cases in 1921.[4] In 1925, Dandy published his first 36 cases of air myelography as a method for detection and localization of spinal cord tumors.[5]

Lipiodol

In 1921, two French internists with some interest in neurology, Sicard and Forestier, were injecting lipiodol into the lumbosacral extradural space for the treatment of inflammatory disease. By accident, they introduced a small amount of this iodinated oil into the subarachnoid space of one patient and immediately recognized the usefulness of this contrast agent in the diagnostic evaluation of the spinal canal. Their discovery, first published in 1922,[6] was widely accepted, and lipiodol myelography became the method of choice for radiographic diagnosis of spinal cord tumors in the 1920's and 1930's. Small amounts of this contrast medium were employed in these early years, usually one quarter to one half c.c. introduced via cisternal puncture with films made in the upright position to locate the site of block. However, shortly thereafter, reports appeared noting the occurrence of adhesions and arachnoiditis due to residual lipiodol. It is probably for this reason that Swedish radiologists have had an aversion to the widespread use of oily contrast media for myelography up to this day. However, American radiologists felt that the advantages outweighed the disadvantages and advocated the use of even larger amounts (up to 3 cc.) in the evaluation of possible spinal cord tumors.

It was not until the historic paper of Mixter and Barr on the clinical significance of the ruptured intervertebral disc in 1934[7] that myelography became a very common procedure. Hampton and Robinson published the first radiological paper on the use of lipiodol for the diagnosis of herniated disc in 1936.[8] They advocated slightly larger amounts of contrast medium (up to 5 cc.), and this initiated further concern regarding the late effects of lipiodol in the subarachnoid space.

In 1939, Adson, a neurosurgeon at the Mayo Clinic, described a method of removing the contrast medium from the subarachnoid space by doing a small sacral laminectomy, incising the dura and then placing the patient erect, thus permitting evacuation of the contrast medium by gravity.[9] Shortly thereafter Kubik and Hampton in 1941[10] described the removal of lipiodol by aspiration through the original puncture needle, and this method is accepted up to the present date. Although lipiodol was not ideal for myelography (not only because of its tendency to promote the formation of arachnoiditis and adhesions, but also because of its rather high viscosity), it was then and is still today a very good contrast medium because of its radiopacity.

The search for a better contrast medium led Nosik to recommend Thorotrast in 1938.[11] However, it was soon apparent that although this colloidal thorium preparation yielded technically satisfactory myelograms, it was quite difficult to remove from the subarachnoid space. Thorotrast, of course, is radioactive with an extremely long half-life, and we are today seeing the unfortunate results of residual Thorotrast in the spinal canal, including nerve root and spinal cord damage as well as the possibility of radiation-induced neoplasms.

In 1940, Camp designed the first 90/90 tilt table for myelography. Up to that time, tilt tables were limited in their motion in one direction to 15/30 degrees. This table was produced by Keleket, and we were fortunate in obtaining one of these tables in 1942 at the Miller Hospital. This greatly facilitated myelography in the thoracic and cervical regions.

Pantopaque

In 1942, the studies of Strain, Plati, and Warren on pantopaque were published.[12] This ethyl ester of iodophenylundecylic acid was not as viscous as lipiodol and thus was easier to aspirate. For the past 25 years, pantopaque has been the contrast medium of choice in this country for myelography. The Swedes continue to work with water-soluble contrast media which do not have to be aspirated.[13] These, however, require spinal anesthesia and thus are limited to examination of the lumbar region. Water-soluble contrast myelography has never become popular in this country. The ideal myelographic contrast medium, of course, would be administered orally, parenterally, or intrathecally and would be completely absorbed from the subarachnoid space after a short period of time with no meningeal reaction.

Technique of Myelography

I believe that myelography should be done in a manner that is painless. Since the contrast medium is not water soluble and must be aspirated at the conclusion of the procedure, introduction of the spinal needle should be done under fluoroscopic control so as to obtain a midline placement. If the needle is in the midline, aspiration of the pantopaque bolus is markedly facilitated. An off-center puncture increases the probability that nerve roots may be impaled during the puncture or aspirated against the needle during aspiration, resulting in radicular pain. It is also best to avoid introducing the needle directly over a disc space; under fluoroscopic control, this is a relatively easy task. In general, it is wise to proceed slowly and gently, advancing the needle in small increments. Once free flow of cerebrospinal fluid is obtained, the needle is advanced another millimeter so that the entire length of the bevelled tip lies within the subarachnoid space. Occasionally, however, the dura or arachnoid may be only partly penetrated by the needle. Further advancement of the needle will then depress the dura or arachnoid, producing defects in the pantopaque column and resulting in a difficult aspiration.

The subdural injection of pantopaque is an occasional complication and should be recognized (Figure 1). When it is recognized, one should never make any type of diagnosis at all other than that one has a subdural injection. Recognition of a subdural injection depends on a fairly sharp almost knifeblade-shaped collection of the contrast medium with indistinct margins.

Most subdural injections are posterior. With the patient prone, the lateral view reveals the contrast medium on the dorsal aspect of the sac. Removal of the contrast medium is difficult, but gentle patient perseverance will usually allow the aspiration of a high proportion of the subdurally injected bolus.

Except in rare instances, no special preparation is required for myelography. However, an occasional patient has so much pain from a disc herniation that he cannot lie on his abdomen for a myelogram. In these cases, it is acceptable to do a puncture in a more comfortable position, aspirate a few cc. of cerebrospinal fluid and dissolve 50 to 75 milligrams of procaine crystals in this fluid. The resulting solution is then reinjected into the subarachnoid space and usually results in very prompt relief of the radicular pain. One can then place the patient prone on the fluoroscopic table and perform a satisfactory myelogram.

Volume of Pantopaque

With regard to how much contrast medium should be used, I have felt more and more in recent years that the quantity should be sufficient to completely outline the sac in the area of suspected clinical abnormality. In the lumbar region, 6 cc. of pantopaque may completely fill a narrow subarachnoid space up to the level of L1. However, in a patient with a very large sac, 50 cc. may barely fill the sac up to the L4-5 disc space. The examination should be tailored to the size of the sac and the location and nature of the suspected abnormality. I do not feel that one should be limited to the use of 6 cc. or any other particular volume. Inadequate volumes of contrast medium in the thoracic region will only outline the anterior aspect of the sac, and le-

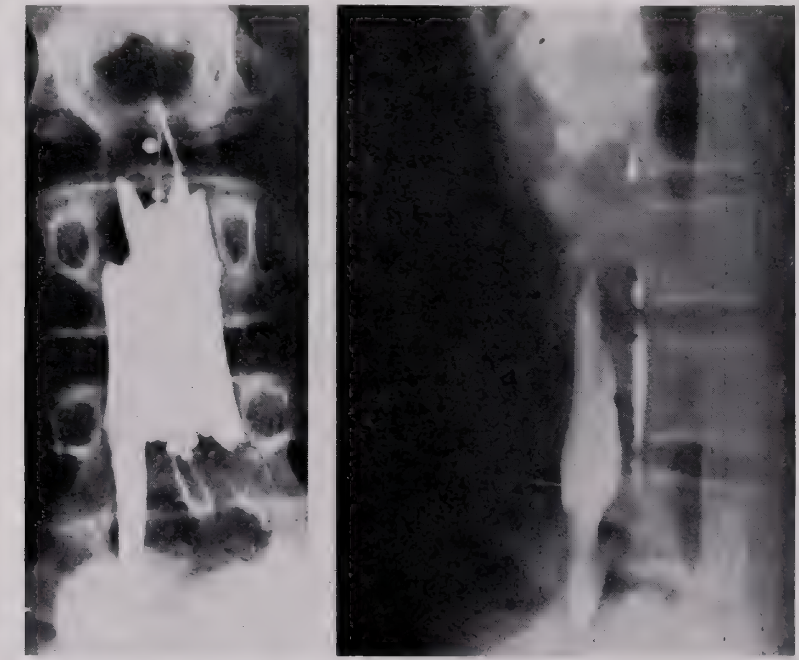

Fig. 1—Subdural injection of pantopaque. (A—left) Anteroposterior view demonstrates sharp almost knifeblade-shaped margins of the collection of contrast medium. There are a few globules of pantopaque which are subarachnoid in location. (B—right) Lateral projection with patient prone shows the subdural contrast medium located posteriorly within the spinal canal. The few droplets in the subarachnoid space lie anteriorly.

sions involving the mid or posterior aspects of the spinal cord will be missed. In the lumbar region, a small amount of pantopaque may pool in the shallow concavities on the posterior aspects of the lumbar vertebral bodies, giving the false appearance of multiple protruding intervertebral discs. Introduction of larger amounts of pantopaque will demonstrate the true anatomy and avoid a false diagnosis of herniated disc. In order to rule out the possibility of an intramedullary arteriovenous malformation, we have used volumes as large as 105 cc. to demonstrate the entire circumference of the spinal cord and thecal sac in the lumbar, thoracic, and cervical regions.

Larger amounts of pantopaque are no more difficult to remove than smaller boli. If there is any difficulty, it usually occurs in aspiration of the last half cc. and the amount of contrast medium employed does not affect this difficulty.

One objection that has been raised to the use of larger amounts of pantopaque is that the rather dense contrast medium (iodine concentration 30%) may obscure underlying lesions. A recent evaluation in our department of a half-strength pantopaque (iodine concentration 15%) failed to substantiate this objection.

Larger amounts of pantopaque are of value in the examination of patients with severe scoliosis, in the demonstration of lesions on the posterior aspect of the thecal sac, and in almost any process other than a complete block which is located in the thoracic or upper lumbar area. Cervical myelography is also greatly facilitated by the use of at least 12 cc. and usually more pantopaque.

The Lumbar Herniated Disc

The classical picture of a herniated intervertebral disc in the lumbar region as described originally by Hampton and Robinson in 1936[8] is still valid. A sharply defined unilateral anvil-like filling defect along the lateral margin of the contrast column at the disc space level is the most valid myelographic finding suggesting herniated intervertebral disc and almost without exception correlates well with surgical findings (Figure 2). This type of deformity is almost always located at the L4-5 level. Nearly 90% of lumbar disc herniations occur at either the L4-5 or L5-S1 levels.[14] The great majority of the remainder occur at L3-4. A lateral projection with the patient in the prone position is often helpful in demonstrating a double shadow on the ventral aspect of the radiopaque column due to a relatively normal posterior disc margin on one side and a more dorsally displaced margin on the side of the herniation. Since the nucleus often herniates through the annulus in a posterolateral direction, anterior

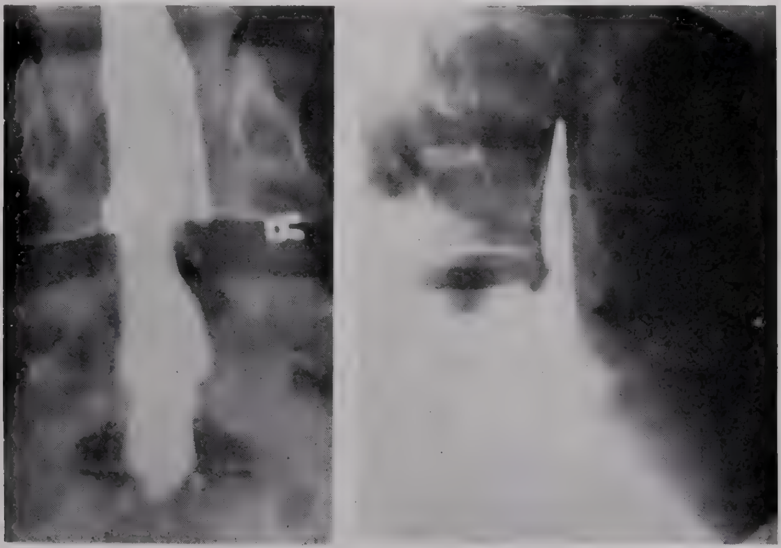

Fig. 2—Herniated intervertebral disc, L4-5 on the right side. (A—left) Anteroposterior view shows sharply defined anvil-like filling defect along lateral margin of pantopaque column at level of L4-5 disc space. (B—right) Lateral projection with patient prone demonstrates a double shadow on the ventral aspect of the radiopaque column due to more dorsally displaced margin on the side of the herniated disc.

oblique views are often of considerable aid in diagnosis.

The pathologic studies of Horwitz in the 1940's established the frequency of bulging and even herniated intervertebral discs in asymptomatic patients.[15] Recent post-mortem discographic and anatomic studies in our department demonstrate a 35% incidence of herniated intervertebral discs at the L3-4 and L4-5 levels in patients above the age of 40. Thus, the mere myelographic demonstration of an extradural anterolateral deformity consistent with a herniated disc is not always the cause of the patient's symptoms. The myelographic findings must always be correlated with the patient's clinical signs and symptoms.

The diagnosis of the occasional herniated disc in the upper lumbar and lower thoracic region requires the use of large amounts of contrast medium so as to build up a "full column" to the level of suspected abnormality. The use of small amounts (6 to 12 cc.) in this region unduly accentuates minor elevations at disc levels which are so common in the older age groups and are usually not significant. The contrast medium tends to pool along the anterior aspect of the sac near the midline in the normally concave curvature of the dorsal aspect of the vertebral body which is accentuated in some individuals. The lateral margins of the intervertebral disc being at a higher level causes a thin pantopaque column to pool toward the midline. On the frontal projection, this results in an hourglass type of deformity which is usually not significant and can be greatly minimized with larger amounts of pantopaque (Figure 3).

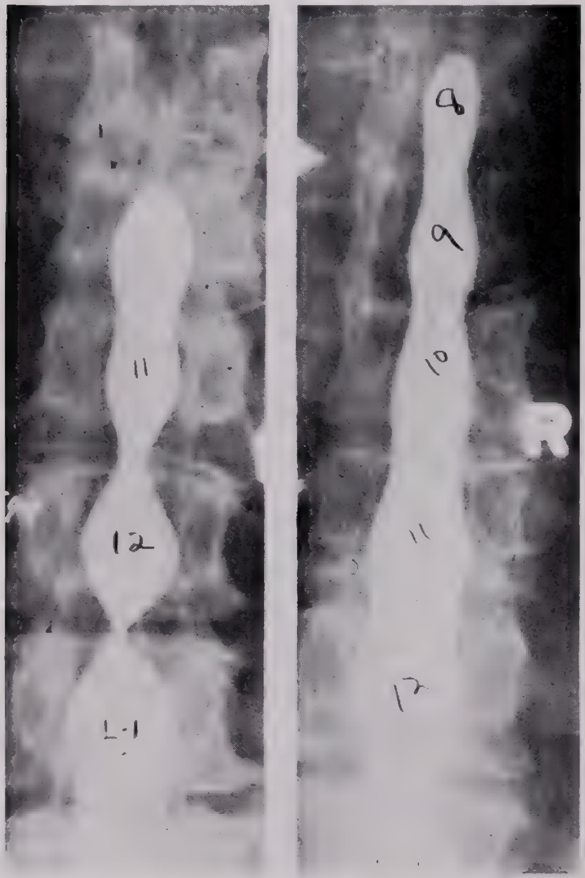

Fig. 3—Hourglass configuration due to small amount of pantopaque. (A—left) 12 cc. pantopaque. Bilateral identations on lateral margins of contrast column at T11-12 and T12-L1. (B—right) 24 cc. pantopaque. The bilateral indentations have disappeared (see text).

The size of the bony spinal canal may cause problems in technique as well as in diagnosis. There is a significantly large number of people who are born with short pedicles and a resultant narrow anteroposterior diameter of their spinal canals. Minor degrees of disc bulging with or without symptoms may produce varying degrees of dural sac compression in these patients

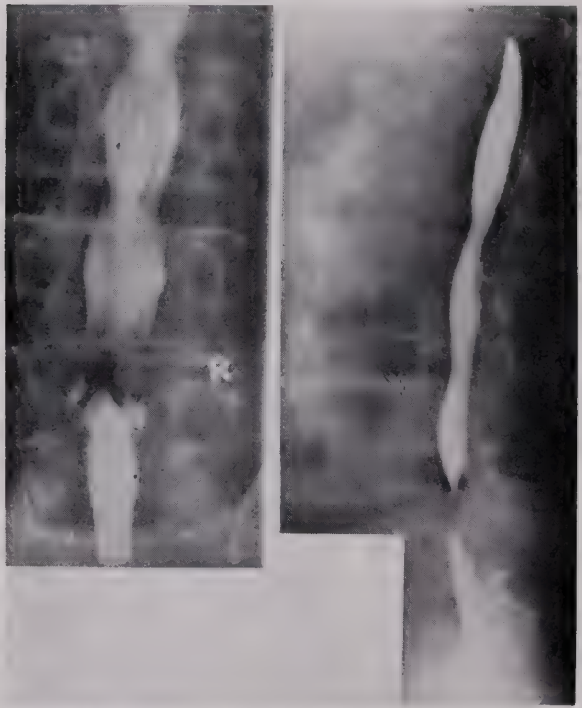

Fig. 4—Narrow anteroposterior diameter of spinal canal. (A—left) Anteroposterior projection. Partial extradural block at level of L4-5 disc space. Note prominence of nerve roots due to thin column of pantopaque. (B—right) Lateral view demonstrates significant narrowing of spinal canal in sagittal plane in lumbar region. Partial block at L4-5 due to disc bulging on anterior aspect and ligamentous thickening posteriorly.

with striking radiographic findings. Myelography may reveal compression of the thecal sac not only from the anterior aspect, but also bilaterally and in some cases even from the posterior surface of the sac (Figure 4). Exploration may reveal marked thickening of the soft tissues in the epidural space, the ligamenta flava posterolaterally, and the soft tissues surrounding the apophyseal joints. It is possible that the relatively minor degrees of trauma to which we are all exposed in everyday life are more significant in such patients because of the narrow spinal canal. Myelography is often very difficult to perform in such patients because of the narrow sac, but a good myelogram may be indispensable to planning an adequate surgical procedure for relief of the chronic and often atypical symptoms with which these patients present.

Recurrence of low back pain, sciatica, and neurological deficits following laminectomy for herniated disc is not rare. However, myelography in such patients is fraught with the possibility of error. Many deformities may be seen postoperatively which may be the result of previous surgical exploration (Figure 5). While one cannot rule out the posibility of a recurrent disc herniation underlying the deformed sac, it is wise not to make this diagnosis unless the deformity is quite classical.

Conclusions

Myelography is an established radiologic procedure for the evaluation and localization of diseases within and affecting the spinal canal. The amount of contrast medium employed in the examination should vary with the size of the thecal sac, the level to be examined, and the nature of expected pathology; but in general larger volumes (more than 12 cc.) will give a more accurate and reliable examination than the small amounts used in an earlier era. Careful meticulous technique with the examination being performed under fluoroscopic control from beginning to end should produce little or no patient discomfort. The diagnosis of herniated intervertebral disc in the lumbar region can usually be accurately made with myelography. However, because of the frequency of asymptomatic disc degeneration particularly in patients beyond age 40, the treatment of the individual case must be based on keen clinical judgment and experience together with a judicious analysis of a technically perfect myelogram.

On the occasion of Dr. Carman's untimely death, his life-long friend and associate Dr. Albert Miller wrote: "The world of the x-ray lost a master workman. For a time it will grieve that he is dead. For a longer time it will rejoice that he lived."

I feel greatly honored that I should be permitted this opportunity of participating in this tradition of the Minnesota Radiological Society which brings to each annual meeting the spirit of one who loved his profession and who exemplified the highest ideals of medicine.

Charles Louis Alphonse Laveran

In recognition of his work regarding the role played by protozoa in causing disease

"On arriving at Bona in 1878 I had the opportunity of making autopsies on subjects who had died from pernicious attacks, and I was struck with the fact that melanaemia was a lesion peculiar to and very characteristic of paludism;* my attention was naturally directed to this lesion, which I had never met in any other disease.

"When one examines a drop of blood taken from the dead body of a palustral subject in the ordinary conditions of autopsy—that is to say, twenty-four hours after death—one sees in the midst of the blood numerous pigmented bodies. Many of these elements are melaniferous leucocytes, the nuclei of which can be coloured and stained with carmine; but besides these leukocytes, hyaline pigmented irregular bodies are seen, which can only be coloured slightly, or not at all, by carmine, and which do not contain any nuclei.

"In 1880, as I was trying to account for the mode of formation of the pigment in the palustral blood, I was led to see that besides melaniferous leucocytes, spherical hyaline corpuscles without nucleus could be seen, and also very characteristic crescent-shaped bodies.

"I had proceeded thus far with my researches, and was still hesitating whether these elements were parasites, when on November 6th, 1880, on examining the pigmented spherical bodies mentioned above, I observed, on the edge of several of these elements, movable filaments of flagella, whose extremely rapid and varied movements left no doubt as to their nature.

"I published in 1881 the observation of the patient in whose blood I saw the flagella for the first time."*

Laveran's discovery of the malarial parasite did not receive immediate recognition from all authorities, but his findings were soon confirmed and extended by others, and his own pathological, clinical, geographical, and therapeutic studies all tended to establish the role of the organisms he had discovered, which later came to be known as plasmodia. Their presence in the blood of malaria patients, their disappearance after treatment with quinine, their absence in healthy persons, and their association with the characteristic malaria pigment made it highly probable that they were indeed the long-sought causative organisms of malaria.†

Worry

Worry, according to a contemporary biochemist, "can be chemically defined as the psychic reaction of somatic saturation with paralytic acid and monosodic phosphate."—Dr. M. N. Eisendrath.

Let's be specific about Campbell's Soups...
and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

SOUP

in acute and chronic diarrheas

LOMOTIL® SAVES...

TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contain:
diphenoxylate hydrochloride .....2.5 mg.
(Warning: May be habit forming)
atropine sulfate, 0.025 mg. (1/2,400 grain)

body fluids...
electrolytes...
patients from exhaustion

Lomotil acts promptly and directly to lower the excessive intestinal motility of diarrhea. This therapeutic restraint on the overactive bowel allows a normal or more nearly normal reabsorption of water and electrolytes.

The proficiency of Lomotil in conserving body fluids and electrolytes often saves patients from the exhaustion that accompanies prolonged diarrhea.

Lomotil acts to control the intestinal mechanisms of diarrhea; therefore, it is highly useful in controlling diarrhea associated with:

gastroenteritis · acute infections · functional hypermotility
irritable bowel · ileostomy · drug-induced diarrhea

Warnings: Lomotil should be used with caution in patients taking barbiturates and with caution, if not contraindicated, in patients with cirrhosis, advanced liver disease or impaired liver function.

Precautions: Lomotil is a Federally exempt narcotic with theoretically possible addictive potential at high dosage; this is not ordinarily a clinical problem. Use Lomotil with considerable caution in patients receiving addicting drugs. Recommended dosages should not be exceeded, and medication should be kept out of reach of children. Should accidental overdosage occur, signs may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is necessary. The subtherapeutic amount of atropine sulfate is added to discourage deliberate overdosage.

Adverse Reactions: Side effects reported with Lomotil therapy include nausea, sedation, dizziness, vomiting, pruritus, restlessness, abdominal discomfort, headache, angioneurotic edema, giant urticaria, lethargy, anorexia, numbness of the extremities, atropine effects, swelling of the gums, euphoria, depression and malaise. Respiratory depression and coma may occur with overdosage.

Dosage: The recommended initial daily dosages, given in divided doses until diarrhea is controlled, are as follows:

Children:	*Total Daily Dosage*
3-6 mo.	½ tsp.* t.i.d. (3 mg.)
6-12 mo.	½ tsp. q.i.d. (4 mg.)
1-2 yr.	½ tsp. 5 times daily (5 mg.)
2-5 yr.	1 tsp. t.i.d. (6 mg.)
5-8 yr.	1 tsp. q.i.d. (8 mg.)
8-12 yr.	1 tsp. 5 times daily (10 mg.)
Adults:	2 tsp. 5 times daily (20 mg.) or 2 tablets q.i.d.

*Based on 4 cc. per teaspoonful.

Maintenance dosage may be as low as one-fourth the initial daily dosage.

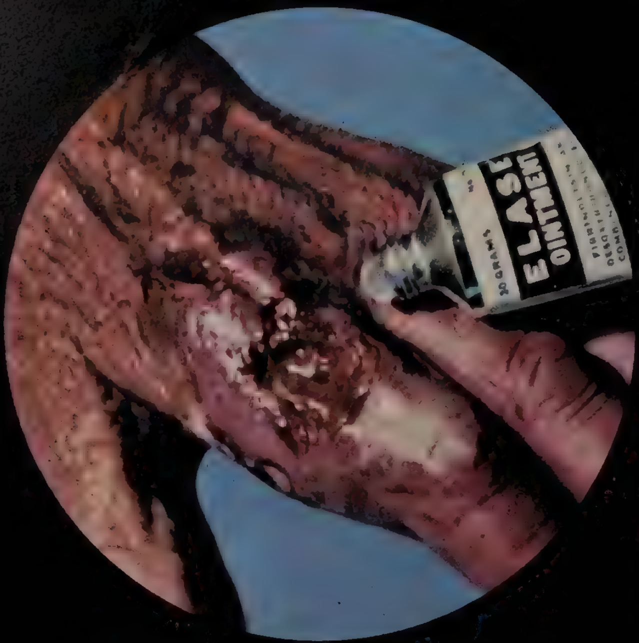
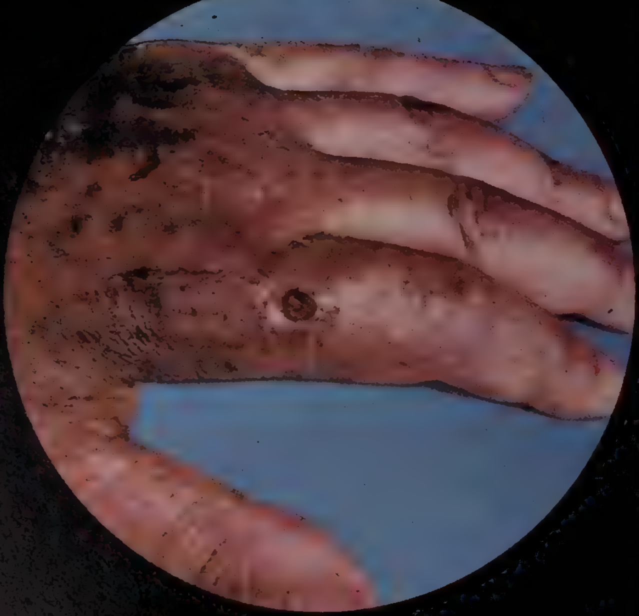
this ulcer did not heal...until its surface was cleared of dead tissue and debris



FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.



to aid in debridement
to facilitate healing
in chronic cutaneous ulcers...

Elase® Ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation...*for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris...the fibrin in blood clots, serum, and purulent exudates...and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

Pulmonary Function

A Study in the Baboon Using Xenon-133 and a Scintillation Camera*

S. H. TSAI, M.D.†
MERLE K. LOKEN, M.D., Ph.D.†
RICHARD PONTO, B.A., R.T.†
PHILIP GRISWA, B.S., R.T.†
Minneapolis, Minnesota

THE XENON-133 TECHNIC of measuring regional pulmonary function represents a significant advance in the study of respiratory physiology. Xe-133 emits a low energy gamma ray of 81 kev. that is suitable for detection by radiation (scintillation) detectors. It is inhaled in gas form for study of ventilation, and injected intravenously in saline solution for study of pulmonary blood flow. Because of its low solubility, the injected xenon evolves into gas as soon as it reaches the lung. Xe-133's short biological half-life permits administration of adequate doses and repeated examinations without undue radiation hazard to the patient. Unlike bronchospirometry, the xenon technique is performed with the patient in sitting position without intubation. The results obtained by the two methods have been very comparable.[6]

In the original methods described by Ball and associates[1] and by West and Dollery[8] multiple scintillation detectors were placed over the chest wall, enabling strip chart recording of the radioactivity of Xe-133 in different zones of the lungs. The recent advent of Anger's scintillation camera has made it possible to cover the entire thorax with a single large scintillation detector and to document the radioactivity of various zones of each lung both graphically on strip charts and pictorially as scintiphotos on Polaroid films.[2,3,5] With proper interface equipment one can advance to computer processing of data. At the University of Minnesota Nuclear Medicine Clinic,[4] data from the scintillation camera are passed directly to a 1600 word memory system which is in the form of a 40 × 40 matrix. From this storage it is transferred at three-second intervals to magnetic tape which is then analyzed using a CDC 3300 computer.

With the increasing interest in organ transplantation it is expected that the xenon technic

will be of value in assessing the function of lung transplants. The present work was initiated to establish a baseline for regional pulmonary function in 12 normal Kenya baboons which will be used in the lung transplantation program at Minneapolis Medical Research Foundation. The anesthetised animal was placed supine in a V-shaped lucite tray which in turn was placed on a wooden rack. The tray and rack were placed directly over the detector head of the scintillation camera.

Method

An endotracheal tube was introduced and connected to a one-liter hand pump via a three-way tap as described by Pain et al.[7] With the cuff inflated and the three-way tap turned off exhaust, the endotracheal tube, the lungs, and the pump formed a closed system (Figure 1). The animal could be made to inhale air delivered from the pump. Breath-holding was achieved by holding the piston down. Rebreathing was done by moving the piston back and forth. To wash the radioactive xenon out of the lungs the animal was made to inhale 500 ml. of fresh air from the pump and exhale passively through the exhaust. This was done 10 times.

Determination of Pulmonary Perfusion

Five to 10 mc. of Xe-133 in 5-10 ml. of saline were injected intravenously. At the end of injection, by means of the pump, the animal was made to inhale 500 ml. of air and breath-hold. As the xenon entered the lungs via the pulmonary artery, the dual chart recorders registered an abrupt rise of radioactivity. When the activity in each lung had reached a plateau (Figure 2-B), the animal was rebreathed 10 times at a tidal volume of 500 ml. (Figure 2-C) to achieve uniform intrapulmonary distribution of the evolved xenon gas. This was followed by a five to six-second period of breath-holding (Figure 2-D) and a subsequent washout procedure (Figure 2-E). A in Figure 2 was the initial background activity; and F, the final background activity. F was greater than A because of contributions from the xenon that had reached the chest wall.

The count rate at plateau B, corrected for initial background, is an index of the blood flow of the lung; while that at plateau D, corrected for final background, the alveolar volume. Dividing the former by the latter one obtains an expression of the *perfusion per unit alveolar volume of the lung.*[7]

Throughout the entire examination the analog data were converted to digital form and taped. Serial scintiphotos were also made on Polaroid films at points corresponding to B, D, and E in Figure 2 (Figure 3).

Determination of Ventilation

Five to 10 mc. of Xe-133 gas were deposited in the lumen of the endotracheal tube. This, together with 500 ml. of air from the pump, was inhaled by the animal. Breath was held until the dual chart recorders showed plateauing of the radioactivity in each lung (Figure 2-B). Rebreathing, a second breath-holding and the final washout process were carried out as in the study for perfusion (Figures 2-C, D, E), as were data conversion, data storage, and scintiphotography (Figure 3).

The count rate at B, corrected for initial background, is an index of ventilation of the lung; and that at D, corrected for final background, the alveolar volume. The ratio of the two represents *ventilation per unit alveolar volume of the lung.*[7]

Results

Relative Pulmonary Perfusion

Five of the 12 baboons had pulmonary blood flow determinations on two occasions, while the other seven were examined only once. There were thus a total of 17 determinations and 34 readings.

The computer was programmed to supply, among other data, left lung/right lung ratios in the following categories: perfusion, alveolar volume, perfusion per unit alveolar volume, and washout half-time (i.e., the number of seconds needed to reduce the corrected count rate at plateau D in Figure 3 by half). A left/right ratio of 1.0 for perfusion would mean a relative blood flow distribution of 50% on each side; a ratio of 0.90, a distribution of 47.3% on the left and 52.7% on the right, etc.

Tables 1 and 2 show the good agreement between duplicate readings in 17 determinations and between readings in animals that had two separate determinations. In either case, the index of *perfusion per unit alveolar volume* was

TABLE 1

Reproducibility of Duplicate Readings in 17 Determinations of Relative Pulmonary Perfusion

Left Lung/Right Lung Ratio	Mean	Standard Deviation
Perfusion:		
1st readings	0.97	0.35
2nd readings	0.94	0.31
All readings	0.94	0.31
Alveolar volume:		
1st readings	0.95	0.23
2nd readings	0.90	0.24
All readings	0.92	0.23
Perfusion/unit alveolar vol.:		
1st readings	1.00	0.16
2nd readings	1.00	0.12
All readings	1.00	0.14
Washout half-time:		
1st readings	1.22	0.50
2nd readings	1.03	0.27
All readings	1.13	0.41

TABLE 2

Reproducibility of Readings on 2 Separate Determinations of Relative Pulmonary Perfusion in 5 Animals

Left Lung/Right Lung Ratio	Mean	Standard Deviation
Perfusion:		
1st determination (all readings)	0.81	0.16
2nd determination (all readings)	0.98	0.31
Alveolar volume:		
1st determination (all readings)	0.84	0.26
2nd determination (all readings)	0.98	0.22
Perfusion/unit alveolar volume:		
1st determination (all readings)	0.98	0.11
2nd determination (all readings)	0.98	0.11
Washout half-time:		
1st determination (all readings)	1.26	0.50
2nd determination (all readings)	1.11	0.45

the most reproducible; the washout half-time, the least reproducible.

The computer was also programmed to give the left/right ratios of perfusion, alveolar volume, perfusion per unit alveolar volume and washout half-time in the upper, middle, and lower thirds of the lung. Tables 3 and 4 compare the reproducibility of readings applicable to the lower thirds. Here the index of perfusion per unit alveolar volume was the most reproducible on duplicate readings in all determination; but less so on two separate determinations in the same animal.

Relative Pulmonary Ventilation

Half of the 12 baboons had a single determination; the other half, two separate determinations. Duplicate readings were obtained at each examination. Reproducibility of the readings was relatively poor except perhaps for alveolar volume (Tables 5 and 6). The data for regional ventilation of the upper, middle and lower lungs showed even wider variations.

Discussion

The present method measures the regional function of each lung, or, with the aid of the data system and the programmed computer, any portion of the lung. Both perfusion and ventilation are evaluated. The readings for perfusion, particularly the *perfusion per unit alveolar volume,* are very reproducible.

TABLE 3

Reproducibility of Duplicate Readings in 17 Determinations of Relative Perfusion of Lower Thirds of Lungs

Left Lower Lung/Right Lower Lung Ratio	Mean	Standard Deviation
Perfusion:		
1st readings	0.93	0.31
2nd readings	0.89	0.29
All readings	0.91	0.30
Alveolar volume:		
1st readings	0.91	0.19
2nd readings	0.89	0.29
All readings	0.90	0.30
Perfusion/unit alveolar volume:		
1st readings	1.03	0.19
2nd readings	1.03	0.27
All readings	1.03	0.23
Washout half-time:		
1st readings	1.00	0.33
2nd readings	1.01	0.24
All readings	1.00	0.29

TABLE 4

Reproducibility of Readings on 2 Separate Determinations of Relative Perfusion of Lower Thirds of Lungs in 5 Animals

Left Lower Lung/Right Lower Lung Ratio:	Mean	Standard Deviation
Perfusion:		
1st determination (all readings)	0.80	0.20
2nd determination (all readings)	0.95	0.30
Alveolar volume:		
1st determination (all readings)	0.82	0.24
2nd determination (all readings)	0.90	0.16
Perfusion/unit alveolar volume:		
1st determination (all readings)	1.01	0.16
2nd determination (all readings)	1.06	0.29
Washout half-time:		
1st determination (all readings)	1.07	0.30
2nd determination (all readings)	1.09	0.34

The poor reproducibility of ventilation values was due to several factors. First, intubation of the short baboon trachea required special care, because either bronchus was easily blocked if the endotracheal tube was placed too low. It was also likely that the bevel of the tube sometimes caused preferential flow of the air and xenon towards the side it was facing. A third factor was the long anesthesia time. The baboons were first anesthetized at the Minneapolis Medical Research Foundation and then transported to the University of Minnesota Nuclear Medicine Clinic for the examination. The minimum total anesthesia time was two and a half hours. During this period secretions sufficient to occlude one or more bronchial branches may have accumulated. We believe that, with a properly placed tube and a dry tracheo-bronchial tree, the repeatability of ventilation readings will be acceptable.

Conclusion

The method as described here should be satisfactory for assessing regional pulmonary function in the experimental animal.

In Memoriam

Death, like birth, is a secret of Nature.—Marcus Aurelius

PAUL H. HEDENSTROM, M.D.

Dr. Paul H. Hedenstrom, 43, head of the Princeton Medical and Surgical Center, was killed October 10 in a light plane crash. Dr. Hedenstrom came to Princeton in 1967, when he joined the McManus Clinic. Prior to that time he had practiced at the St. Cloud Hospital, where he was a member of the Surgical Privileges Committee. He was also consulting surgeon for St. Gabriels Hospital in Little Falls.

Certified by the American Board of Surgery as a diplomate, he was also a member of the American Medical Association, the Minnesota State Medical Association, and the Stearns-Benton County Medical Society.

Dr. Hedenstrom is survived by his wife, a son and daughter.

KEITH D. LARSON, M.D.

Dr. Keith D. Larson, 54, former medical director of the Moose Lake State Hospital, died suddenly September 21, in Washington. He was a native of Clintonville, Wisconsin, and graduated from Lawrence College, Appleton, and Northwestern University Medical School in Chicago. He interned at the Presbyterian Hospital in Chicago and took his residency at the Cook County Hospital. Later he received his fellowship at the Mayo Clinic specializing in neurology, psychiatry and internal medicine.

Dr. Larson is survived by his wife and three daughters.

HOWARD M. FRYKMAN, M.D.

Dr. Howard M. Frykman, 52, Minneapolis proctologist, died October 2. Born in Souris, North Dakota, he attended the University of Minnesota Medical School.

Dr. Frykman was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society.

He is survived by his wife and children.

FREDERICK L. SMITH, M.D.

Dr. Frederick L. Smith, 90, emeritus head of the section of the postoperative treatment at the Mayo Clinic, died September 14, of a heart ailment. Born in Waseca, Minnesota, Dr. Smith attended the University of Minnesota Medical School.

His professional affiliations were numerous, including membership in the American Medical Association, the Alumni Association of the Mayo Foundation, the Association of the Military Surgeons of the United States. He was a charter member of the Minnesota Academy of Science and a former president of the Olmsted County Medical Society. Dr. Smith was an Associate and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, one daughter and two sons, one of whom is Dr. Frederick A. Smith of Bath, New York.

EDWARD R. ADDY, M.D.

Dr. Edward R. Addy, 69, Gilbert physician, died July 9, after a lingering illness. Born in Northville, North Dakota, he attended the University of Minnesota Medical School and interned at St. Mary's Hospital in Duluth. He came to Gilbert in 1933, where he practiced medicine until the time of his illness.

He was a member of the American Academy of General Practice, the American Medical Association, the Minnesota State Medical Association and the Range Medical Society.

He is survived by his wife.

FRANK J. HIRSCHBOECK, M.D.

Dr. Frank J. Hirschboeck, 82, Duluth physician, died October 15. He had been associated with the Duluth Clinic for forty-four years. His medical degree was received from Marquette University.

He was active in professional circles and prominent as a speaker on medical subjects and other topics. For ten years he advised University of Minnesota School of Medicine graduates on "Medical Ethics and Medical Practice," and for many years participated in a speakers' panel sponsored by the medical school.

Dr. Hirschboeck was a former president of the St. Louis County Medical Society, the Minnesota Society of Internal Medicine, the Minnesota Branch of the American Heart Association, the Inter-Urban Academy of Medicine and the Minnesota Society of Diseases of the Heart and Circulation. He was also a member of the American Medical Association and the St. Louis County Medical Society and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by two daughters and one son.

ELMER O. DAHL, M.D.

Dr. Elmer O. Dahl, 78, Minneapolis specialist, died November 5. A graduate of Loyola University, Dr. Dahl practiced medicine with his brother, Dr. John A. Dahl, in Minneapolis.

He was a member of the Hennepin County Medical Society, American Medical Association, American College of Ophthalmology and Otolaryngology and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife.

CARL J. T. LUND, M.D.

Dr. Carl J. Lund, 64, Fergus Falls physician, died October 16. Born in Saronville, Nebraska, he attended the University of Minnesota Medical School.

He was a member of the local school boards, the Lutheran Church of America, the Board of Gustavus Adolphus College, the American Medical Association, the Minnesota State Medical Association, and the Park Region District and County Medical Society.

He is survived by his wife, three daughters and two sons.

Admission Chest Film Program

Fifteen Years' Experience

L. M. HAMMAR, M.D.
Mankato, Minnesota

Is it justifiable to routinely x-ray the chest of every patient admitted to a general hospital? Is the information gained sufficiently valuable to warrant retention of the program? How productive is the study in detection of tuberculosis and other diseases? Have any serendipitous* effects accrued? What are the difficulties in administration of the program? These are the questions that need answers. Little has been published on the success or failure of the program in Minnesota since its inception in the early 1950s. It is hoped that analysis of our experience in a small general hospital (126 beds) may shed some light on the matter.

Background and Scope of the Program in Minnesota

On May 16, 1953, under the leadership of J. F. Briggs, M.D., and J. A. Meyers, M.D., the Council of the Minnesota State Medical Association recommended that a program of routine admission chest roentgenograms be instituted in all hospitals of the state. By 1965, 86% of the general hospitals in Minnesota required routine admission chest x-rays.[1] These hospitals admitted 549,550 patients or 91% of the patients entering general hospitals in Minnesota.

Instituting the Program

The policy of requiring an admission chest film was instituted at Immanuel Hospital, Mankato, Minnesota, in October, 1953. To make the program as inclusive as possible, no exceptions were permitted unless the patient had had a previous chest film within the last six months at either the hospital or the physician's office. Obstetrical patients were x-rayed as soon as possible after delivery. All others were filmed at the time of admission if their condition permitted. Many surgical patients at our hospital are admitted during the late afternoon; their chest films are taken at the time of the laboratory workup and interpretation is always available prior to surgery the next morning.

---

*See Test Your Word Score Page 1921.

If an abnormality which would make anesthesia or a surgical procedure hazardous is detected, the surgeon is informed. Newborn infants are not routinely x-rayed. Very ill patients, some emergency cases and some transfers from other hospitals will occasionally be in the hospital for extended stays without admission films. In the 15 years covered by this report, there were 63,298 admissions and 36,475 admission chest roentgenograms.

Convincing the attending physician that his patient should have a routine admission chest film was sometimes difficult. "If I want my patient to have a chest x-ray, I'll order it." was the frequent objection. Cost to the patient was also mentioned. Unnecessary exposure to radiation, especially for obstetrical and pediatric patients, became frequent objections during the wave of apprehension concerning "fall-out" radiation in the late 1950s. Discussion of these problems at hospital staff meetings, programs showing actual cases benefited by admission chest roentgenograms, taking films of obstetrical patients after delivery, shielding gonadal regions in pediatric patients, all helped to overcome the objections. Cost to the patient was held to the lowest possible figure. Initially we charged $4.00 for a 14 × 17″ film; in 1964 the charged was increased to $5.00, and in 1968, to $6.00 for the examination.

Results

The initial emphasis was on tuberculosis case finding. A high percentage of patients admitted to our type of hospital is in the geriatric range, and this segment of population is most apt to be harboring tuberculosis as a carry-over from the time it was much more prevalent. Review of our cases after the first 14 months (1635 admission films) showed discovery of one active case of pulmonary tuberculosis and seven inactive cases. With this start, we were encouraged to continue. Tabulation of other conditions revealed by admission chest films during the same initial period showed many serendipitous findings which further justified continuation of the program.

The accompanying table lists the most commonly encountered x-ray findings. Minor degrees of cardiac enlargement or early arteriosclerotic changes in the aorta were not listed

TABLE

Abnormalities Detected on Admission Chest Films

Condition	Times Found
Tuberculosis	
Active; cases not previously known	13
Inactive; old cases previously known	31
Suspected; not subsequently proven	23
Chest Conditions (non-tuberculous)	
Sarcoidosis	4
Pneumonia	355
Pneumonia in patients scheduled for surgery	16
Pleural effusion	23
Infarction	24
Abscess	4
Pneumothorax	5
Bronchial obstruction with lobar collapse	14
Foreign body (unsuspected)	3
Hilar adenopathy	42
Substernal thyroid	31
Mediastinal emphysema	1
Emphysema	19
Chest Conditions (neoplastic)	
Tumor in lung parenchyma (solitary)	39
Tumors, multiple, metastatic	61
Rib tumors	12
Mediastinal tumor	5
Heart and Aorta	
Pulmonary edema	4
Severe cardiomegaly	22
Arteriosclerotic heart disease	57
Heart and Aorta (continued)	
Mitral disease	17
Combined arteriosclerotic and mitral disease	11
Intra-cardiac calcification	2
Cor pulmonale	1
Pericardial calcification	1
Luetic aortitis	2
Aortic aneurysms	7
Pericardial effusion	3
Coarctation of aorta	2
Congestive heart failure	62
Anomalies	
Dextro-cardia	3
Right descending aorta	4
Cervical ribs	12
Funnel chest	2
Hepato-diaphragmatic interposition of colon	8
Atrial septal defect	1
Patent ductus arteriosus	1
Miscellaneous	
Myelofibrosis	1
Kyphoscoliosis (severe)	14
Subdiaphragmatic abscess	1
Fibrous dysplasia of rib	1
Air under diaphragm (unsuspected)	7
Diaphragmatic hernia	11
Addison's disease	2

or included in the table. A total of 1012 abnormalities was found in the 36,475 cases examined.

The table lists the most commonly encountered x-ray findings. Those listed as active tuberculosis were previously unrecognized cases, in which acid-fast organisms were seen in smears or demonstrated in cultures or guinea-pig innoculations. All but one of these active cases were over 50 years of age. The 31 inactive cases had all been diagnosed and treated previously, and pronounced arrested. The 23 listed as suspected but not subsequently proven cases had x-ray findings strongly resembling tuberculosis. Most of them received intensive study, including gastric washings and cultures. The remaining conditions listed in the table are x-ray diagnoses and most of them are self-explanatory. They were included only if reasonably clear-cut evidence was seen on the film, and if the condition was of possible clinical significance. Minor degrees of cardiac enlargement or early arteriosclerotic changes in the aorta were not listed. Many conditions seen on the films are not included in the table. A total of 1012 abnormalities was found in the 36,475 cases examined.

Comments

There is a small but significant segment of our older population still affected with active unknown tuberculosis. Sooner or later, most of these individuals are admitted to a hospital. The admission chest roentgenogram is an effective method of detecting these cases.

Transmission of tuberculosis to other hospital patients and especially to nurses may be circumvented.

Sixteen patients scheduled for surgery were found to have pneumonia or other pulmonary pathology contraindicating inhalation anesthesia.

Extra dividends from the program are the detection of numerous clinically significant and unsuspected conditions.

Small Blood Vessel Syndrome

Constitutional Arterial Narrowing

THOMAS E. JOHNSON, M.D.*
St. Paul, Minnesota

THE GRADING OF PERIPHERAL PULSES is a necessary part of all physical examinations. It provides a base line reference for the future as well as an estimation of the current status of a patient's blood vessel health. For the angiographer a pre-angiographic record of the peripheral pulses is mandatory. An estimation of the blood vessel size and possible anatomical variations to be encountered can provide for fast, safe and accurate diagnosis during subsequent angiography.

Young female adults are known by angiographers to possess small, elastic blood vessels. Patients with short stature and mild truncal obesity have an even greater degree of constitutional narrowing as well as a frequent important anatomical variation of the common femoral artery. This narrowing predisposes them to symptomatic occlusive disease at an early age.

The Material

In an analysis of 21 exemplary patients, 14 were under 50 years of age; eight of 14 suffered from symptomatic occlusive disease; seven required surgical corrective procedures; four were less than 41 years of age. Average height and weight was five feet, two inches and 124 pounds.

The Findings

Without correction for magnification as produced by x-ray projection, average measurement of the aorta-ilio-femoral lumen in these patients is listed (Table 1), and illustrated in the composite (Figure 1). They have a normal-diameter lower dorsal aorta,[1,2] however; a comparison with Steinberg's[1] 500 patients reveals an exaggerated tapering of the caudal aorta below the renal arteries in constitutional narrowing. Major extremity arteries have a similar reduction in size not due to atrophy secondary to proximal stenosis. An average normal patient has a common femoral

(Bottom) Right femoral artery: 0.6 × 4.5cm.
Left femoral artery: 0.6 × 1.0cm.
Superficial femoral artery: 0.4cm. wide

artery which is 1.0 cm wide and 6.0 cm long.

TABLE I

	Steinberg-Normal Aorta (±0.3 cm)	Constitutional Narrowing Average
At T-12	2.44 cm	2.0 cm
Above renal arteries	2.16 cm	1.8 cm
Below renal arteries	1.87 cm	1.5 cm
At bifurcation	1.75 cm	1.2 cm
Common femoral		0.6 cm × 3.0 cm
Popliteal		0.35 cm

Literature

Wertheimer[3] has theorized that congenital narrowing of vessels results in a secondary increase in peripheral resistance giving rise to intimal thickening and thrombosis on the same basis as in primary or secondary pulmonary hypertension. Clemetson[4] has reviewed a possible correlation of pre-eclamptic toxemia of pregnancy with the presence of a small abdominal aorta in five of eight patients. All were less than five feet three inches tall and had mild truncal obesity. Hypertension was not a frequent finding in any of our 21 cases and, when present, was explained with one exception by renal artery stenosis or occlusion or chronic pyelonephritis. Obstetrical histories in four patients were normal and not obtained in the rest.

It would be misleading to describe these patients as having aortic hypoplasia.* Most such cases are associated with abdominal coarctation, tubular hypoplasia, supravalvular aortic stenosis or other complicated congenital cardiovascular problems. The small vessel syndrome is commonplace, whereas a true hypoplasia is a rarity as shown by Ikeda's discovery of eight cases in 14,000 autopsies.[6]

Significance

A frequent erroneous downgrading of peripheral pulses is observed in these patients. This is due to a combination of the following factors: (1) a short narrow common femoral artery; (2) high bifurcation of the common femoral artery; (3) tiny anterior and posterior tibial arteries.

In one half of these patients the common femoral artery was less than 3 cm long. Digital examination in the usual location therefore causes one to palpate the smaller superficial femoral artery instead of the common femoral artery in the groin. This can give the examiner the false impression that the femoral pulse is diminished over expected. The bifurcation anomaly is not always bilateral; therefore one femoral pulsation may seem diminished to palpation as compared to the other, or both may seem of abnormally low amplitude when in fact both are normal for the size of vessel present. Palpation must be done high in the groin, close to the inguinal ligament.

---

*See Test Your Word Score Page 1921.

The tibial arteries, although adequate for the patient, can be the size of a small thread and may be very difficult to feel at the ankles. A very delicate palpating touch is necessary for accurate peripheral pulse grading. Several patients herein reported have had angiographic examinations because of vague leg symptoms or varicosities and "absence" or "diminution" in one or more of the ankle pulses; therefore arterial occlusive disease was suggested where none existed.

The ankle pulses must be checked throughout the examination. In addition, these small vessels have a strong tendency to go into spasm, either at the needle puncture site or around the catheter. This spasm may be located at the femoral insertion site, but we have also observed severe pericatheter spasm of the entire iliac artery.

It is desirable to use heparinized saline for catheter flushing even though one is not performing an examination above the diaphragm.

Catheters which are formed for selective arteriograms of various body organs must be made with a much smaller curve at the tip since these small aortas will hold the tip straight and not allow it to curve into the desired course. The catheters themselves should have the smallest outside diameter consistent with a diagnostic examination.

The most important point is the fact that a very small amount of atheromatous tissue can produce a very significant constriction of the lumen of these vessels; therefore these patients tend to become symptomatic while disease is well localized and minimal in nature. As mentioned, eight patients had symptomatic occlusive disease before 50 years of age. One should keep in mind that young females with this body habitus who have vague or even typical symptoms of extremity ischemia should not be ignored because of their age and sex. Close appraisal of these symptoms should be made along with the peripheral pulse examination.

When the more severe form of small abdominal aorta or iliac artery is encountered with localized atheromatous partial occlusion, one should consider an aorto-iliac replacement by prosthesis rather than localized endarterectomy. Two of these patients who underwent abdominal aorta endarterectomy required repeat surgery within two years of the original operation, due to progression in size of small atheromatous deposits elsewhere between the renal arteries and the aortic bifurcation (Figure 1).

Summary

Short female patients who have mild truncal obesity show a significant incidence of constitutional arterial narrowing. This can be normal for a given patient but predisposes her to symptomatic degenerative disease at an early age. It is frequently associated with high bifurcation of the common femoral artery, diminutive ankle pulses and a definite tendency for spasm secondary to direct trauma by needle or catheter. During the physical examination, recognition of these patients is possible with a fairly high degree of accuracy. Erroneous conclusions regarding the adequacy of peripheral pulsations can thus be prevented.

When angiographic diagnosis is necessary, the size of the arterial tree and the anatomical pattern to be encountered are predictable, thus allowing the selection of appropriate instruments, puncture site, and catheter form. Unnecessary catheter exchanges and superficial femoral artery obstruction during arteriography can be prevented. In some instances, aorto-femoral bypass graft is preferable to limited aortic endarterectomy even though the disease is limited to a small segment of the aorta or iliac artery.

References may be secured from the author or the reprints.

Many a family tree needs trimming.—Frank Hubbard

Meetings and Announcements

American Board of Family Practice

The American Board of Family Practice announces that it will give its FIRST examination for certification in various centers throughout the United States. The examination will be over a two-day period on February 28-March 1, 1970. Information regarding the examination and eligibility for the examination can be obtained by writing: Nicholas J. Pisacano, M.D., Secretary, University of Kentucky Medical Center, Annex #2, Room 229, Lexington, Kentucky 40506.

Clinical Neurology Fellowships

Fellowships in Clinical Neurology have been established at the Minneapolis Veterans Administration Hospital.

General Practitioners and Non-Neurological Specialists are invited to apply for an intensive postgraduate training experience on the Neurological Wards at the Minneapolis VA Hospital. Programs are designed to provide one to four weeks of supervised bedside and didactic instruction in the diagnosis and treatment of neurological disease. Those accepted for the fellowship may receive quarters, if desired. Fellows may elect any one or a combination of the following programs:

Week 1—The Neurological Examination
Week 2—Special Neurological Diagnostic Procedures
Week 3—Latest Treatments of Acute and Chronic Neurological Problems
Week 4—Frontiers of Neurological Research

Each program will commence on Monday and terminate on Friday.

Apply to Milton Alter, M.D., Ph.D., Chief, Neurology Service, Veterans Administration Hospital, 54th St. and 48th Ave. So., Minneapolis, Minnesota 55417.

Minnesota Heart Association

Heart symposium, Saturday and Sunday, January 24-25, sponsored by the Minnesota Heart Association at the St. Paul Hilton Hotel, St. Paul, Minnesota. Topic: What To Do About High Blood Pressure? Chairman: Kenneth G. Berge, M.D.; Time: January 24th, 8:30 to 4:30 and January 25th, 9:00 to 12:00.

February Meetings

Hennepin County Academy of General Practice Chapter Meeting, February 16 at the Minneapolis Athletic Club.

Minnesota Academy of Occupational Medicine and Surgery, February 19th at the Minneapolis Club, 729 Second Avenue South, Minneapolis, Minnesota. Program Chairman: Edwin G. Benjamin, M.D.

Don't knock the weather; nine tenths of the people couldn't start a conversation if it didn't change once in a while.—Frank Hubbard

Inner Sites...

In Cystitis...Azo Gantanol® focuses analgesic-antibacterial activity where it counts

Blood and urine: therapeutic antibacterial levels within 2 hours for up to 12 hours

Gantanol (sulfamethoxazole) produces prompt and prolonged therapeutic levels, in both blood and urine, with convenient *b.i.d.* dosage. Clinical response is usually obtained within 24 to 48 hours. The wide antibacterial spectrum of Gantanol includes *E. coli* and a variety of other susceptible gram-negative and gram-positive pathogens in urinary tract infections.

The mucosa: specific analgesia usually within 30 minutes

Azo (phenazopyridine HCl) effects specific mucosal analgesia, relieving the dysuria, discomfort and burning which are virtually always a part of acute urinary tract infections.

Interstitial fluids: ready diffusion of antibacterial

Gantanol (sulfamethoxazole) is readily diffused into interstitial fluids to provide efficient antibacterial activity at foci of infection. This distribution, plus continuous antibacterial levels in blood and urine, has afforded effectiveness in the majority of infections in which it has been used.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Urinary tract infections with associated pain or discomfort when due to susceptible organisms; prophylactically in urologic surgery, catheterization and instrumentation.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, newborn infants during the first three months of life, glomerular nephritis, severe hepatitis, uremia and pyelonephritis of pregnancy with gastrointestinal disturbances.

Warnings: Use only after critical appraisal in patients with liver damage, renal damage, urinary obstruction or blood dyscrasias. If toxic or hypersensitivity reactions or blood dyscrasias occur, discontinue therapy. In closely intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed.

Precautions: Observe usual sulfonamide therapy precautions including maintenance of an adequate fluid intake. Use with caution in patients with histories of allergies and/or asthma. Patients with impaired renal function should be followed closely since renal impairment may cause excessive drug accumulation. Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections.

Adverse Reactions: Headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, Stevens-Johnson syndrome, injection of the conjunctiva and sclera, petechiae, purpura, hematuria or crystalluria may occur, in which case the dosage should be decreased or the drug withdrawn.

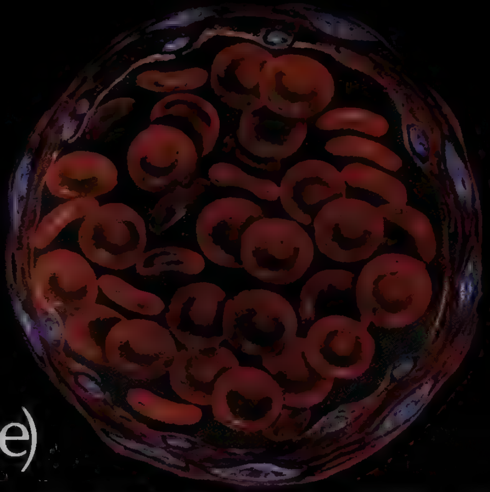
Azo Gantanol®

(Each tablet contains 0.5 Gm sulfamethoxazole and 100 mg phenazopyridine HCl.)



Roniacol Timespan
(nicotinyl alcohol tartrate)

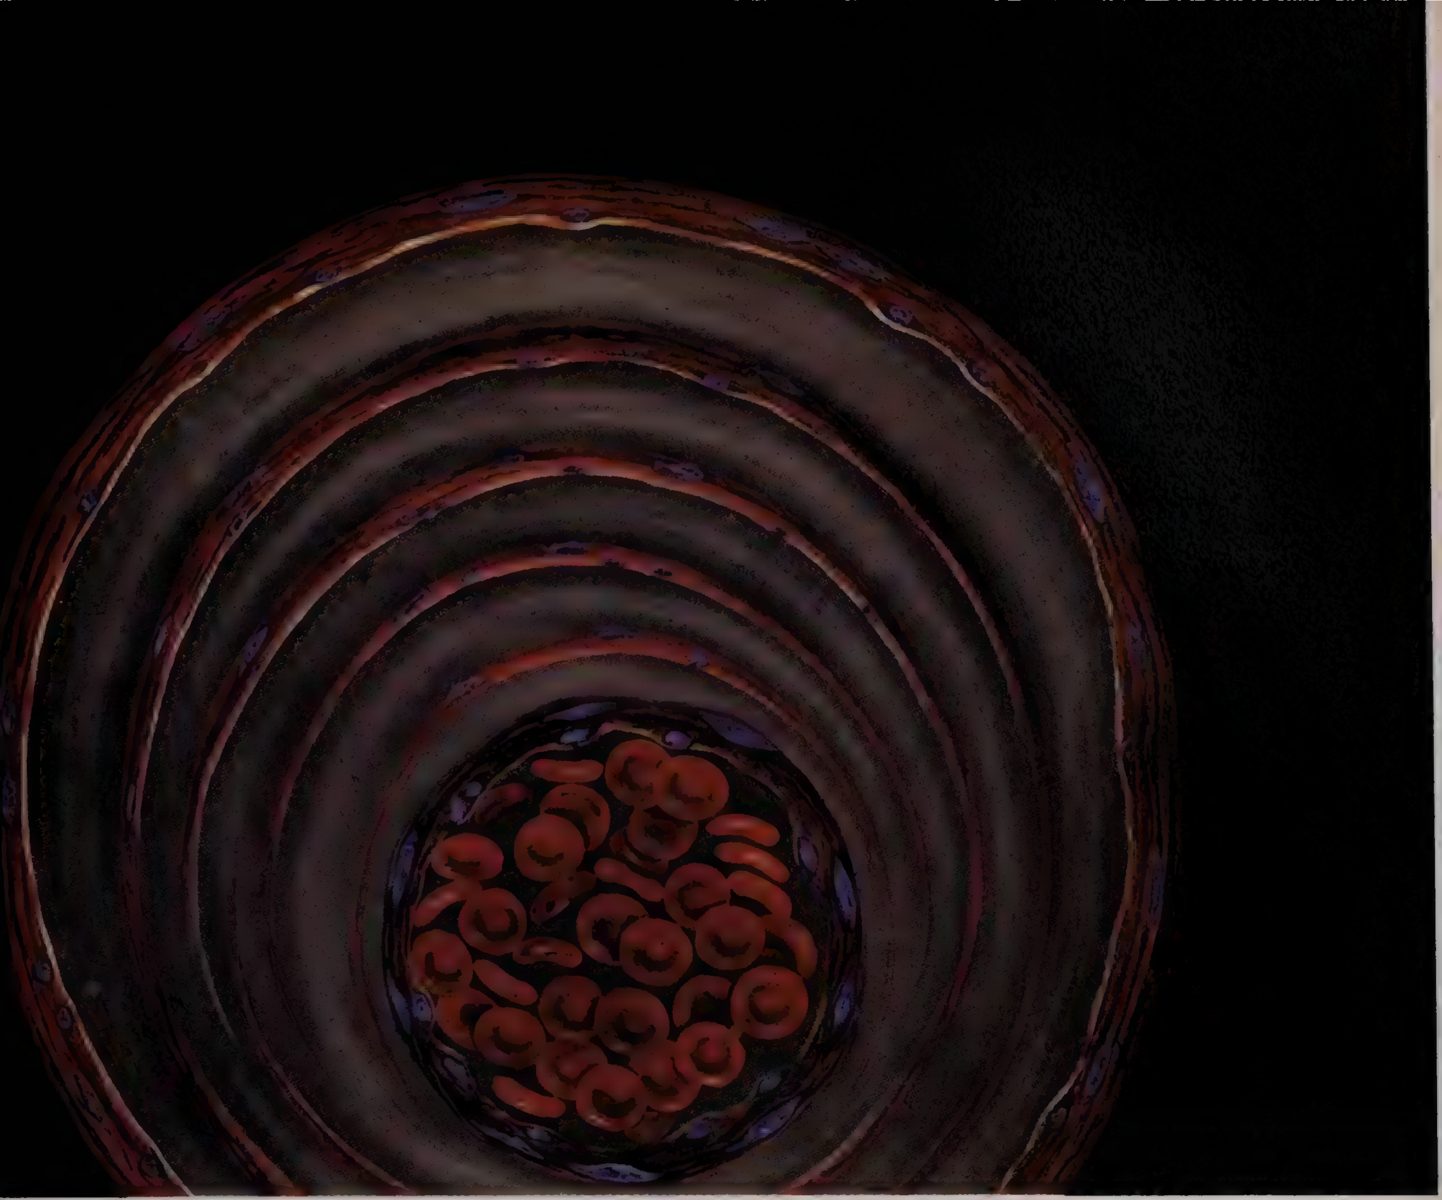
Because peripheral vasodilation is needed now... and must often be continued

Roniacol Timespan (nicotinyl alcohol tartrate) can make a significant contribution to effective treatment of peripheral vascular disorders. It is directed specifically toward improvement of peripheral blood flow, relief of ischemic symptoms, and the long-term management of these conditions.

Specific pharmacologic action—Roniacol (nicotinyl alcohol) acts selectively by relaxing smooth muscle of peripheral blood vessels. Onset of action is smooth and gradual, rarely causing severe flushing.

Relative freedom from side effects—Side effects that may occur occasionally with Roniacol seldom require discontinuation of therapy.

Prolonged, continuous drug release—Prolonged peripheral vasodilation is provided by sustained-release Roniacol Timespan (nicotiny alcohol tartrate) Tablets. Part of the drug becomes available immediately, the remainder continuously over a period of up to 12 hours, and dilation of constricted peripheral vessels i usually maintained. Thus, with a single dose o medication, patients can enjoy the benefits of increased peripheral blood flow in ischemic extremities for up to 12 hours.



Smooth peripheral vasodilation from initial dosage...extended with simple, well-tolerated, b.i.d. dosage

The prolonged action of Roniacol Timespan (nicotinyl alcohol tartrate) together with its other benefits offer a therapeutically practical measure in the long-term management of peripheral vascular disease—advantages especially important for older patients.

Before prescribing, please consult complete product information, a summary of which follows:

ndications: Conditions associated with deficient circulation; e.g., peripheral vascular disease, vascular spasm, varicose ulcers, decubital ulcers, chilblains, Meniere's syndrome and vertigo.

Caution: Roche Laboratories endorses caution in the administration of any therapeutic agent to pregnant patients.

Side Effects: Transient flushing, gastric disturbances, minor skin rashes and allergies may occur in some patients, seldom requiring discontinuation of the drug.

Dosage: 1 or 2 Timespan Tablets—150 mg nicotinyl alcohol in the form of the tartrate salt—bottles of 50 and 500.

Editorials

The First Time

This is the first time that Members of the Minnesota Radiological Society pool their works in a single issue of Minnesota Medicine. The result is an eloquent illustration of the scope and depth of the specialty of Radiology.

This collection of articles is also a fitting tribute to an eminent radiologist and a much respected teacher, Dr. Harold O. Peterson, himself a contributor to this issue.

Thanks are due the Editorial Staff of Minnesota Medicine for their help and cooperation, and the members and officials of the Society for their enthusiasm and support.

Radiology

Responsibilities and Opportunities

Within the past decade, radiology has gained increasing importance and stature within the medical community.* There are today in the United States approximately 8,000 radiologists. The recent report of the National Advisory Committee on Radiation estimates that by 1975 this country will need 25,000 practicing specialists in radiology.

The responsibilities and opportunities of a University Department of Radiology lie in undergraduate education, graduate training, and fulfillment of community needs.

Not many years ago, most residents were older practicing physicians; today they are medical students. The choice of radiology as a career was often related to the lessened physical demands upon the individual as compared with other clinical disciplines. Today this is no longer true. The growth of angiography has contributed much to this change, but we must also credit the increase in knowledge gained from the basic sciences and various clinical specialties. The academic Department of Radiology must offer a strong undergraduate teaching program, not only to attract good people, but also to instruct the future practitioner where and how radiology may aid in the diagnosis and treatment of his patients.

In a sense, every radiologist is a teacher. Increasingly, radiology is a hospital base specialty, and the physician on his daily rounds seeks the aid and advice of the radiologist. The demand for community radiologists creates an even more pressing need for astute teachers and investigators. An academic department must offer opportunities for basic and clinical research; an atmosphere where inquiry is encouraged. Furthermore, increased knowledge in all areas of radiology has stimulated the development of subspecialties such as neuroradiology, cardiovascular radiology, and pediatric radiology.

The shortage of radiologists requiring specialized training is attaining alarming proportions. It is evident that in order to fulfill our responsibility we will have to not only train more radiologists but also develop better methods of utilization of these valued specialists. Reevaluation of the classical methods of radiological practice, better use of technicians by offering specialized training in areas which were until now considered strictly within the scope of the radiologist, and analysis of technological advances are all under study.

In order to meet the need, the University of Minnesota Integrated Residency Program in Radiology is at present training 65 radiologists, by far the nation's largest radiology residency program; and to further combat the shortage, close affiliation is being developed with other hospitals in the community interested in undergraduate and postgraduate training. The Minneapolis Veterans Administration hospital, Hennepin County General Hospital, and St. Paul-Ramsey Hospital already form an integral part of this program. Additional affiliations, where such affiliation is of mutual interest and benefit, are being sought. Furthermore, it is our feeling that members of the local radiological community, can and should participate actively in the graduate training program. At present, over 40 radiologists in the Twin Cities area hold clinical staff appointments in this department.

In 1937, under the guidance of Dr. Leo G. Rigler, this department established the first postgraduate continuation course in radiology in the nation. This course has been held each fall for over 30 years, always attracting a large enrollment from all parts of the United States and Canada. The University is in a position to develop this area of continuing education even further. One area presently being explored would be allowing practicing radiologists to return on a voluntary basis to the academic center periodically to learn new techniques and update their knowledge. It may even be possible to provide reasonable coverage (probably in the form of adequately trained residents) to permit the practicing radiologist time away from his practice to participate in such activities This continuing education

should encompass not only diagnostic radiology and its various subspecialties, but also the fields of nuclear medicine and radiation therapy. Similar courses could be developed for radiologic technicians. Support for these undertakings could reasonably be expected from regional medical programs. These activities offer the possibility of improving not only the quality of radiology but also the relationships between the University and the private sector of radiology, for it is my opinion that these lines of communication should and must be improved.

Where knowledge is weak, prejudice often becomes strong. Academic radiologists must never become blind to the needs of the community. On the other hand, the practicing radiologist should not only recognize the nature and responsibilities of academic radiology, but wherever possible aid us in our tasks. If we act from a position of mutual respect and understanding, both the University and the community will benefit. Together, the proud heritage of Minnesota Radiology will be preserved and the challenges of the future will be met.

E. Gedgaudas, M.D.*
Minneapolis, Minnesota

---

*Professor and Head Department of Radiology, University of Minnesota Hospitals.

Eugene Gedgaudas, M.D.

Dr. Eugene Gedgaudas, who succeeds Dr. Harold O. Peterson as Head of the Department of Radiology at the University of Minnesota, was born in Lithuania and received his premedical education in Lithuania before entering medical school in Germany, graduating from the University of Munich in 1948. He took his training in radiology in Canada and at the University of Minnesota.

Joining the full-time staff of the University in 1963, he became Head of the Department of Radiology on October 1, 1969. He is the third man to head the department since it was established in 1935. Dr. Leo G. Rigler headed the Division of Radiology in 1927 and in 1935 was made Chief of the Department.

Dear Doctor:

Two common geriatric and pre-geriatric vasospastic states, cerebral ischemia and myocardial ischemia, have been shown to be helped by papaverine when administered in a form which provides gradual release of the drug. Just such a form for continued release is found in **VASOSPAN** containing 150 mg. of papaverine hydrochloride in an efficient sustained-release capsule.

"Emphasis on Flow" is the aim of treatment and the accomplishment of **VASOSPAN** in these conditions. And it's done economically, too—a matter of no little importance to the geriatric or pre-geriatric patient. With **VASOSPAN** there is a comparatively rapid early release for prompt relief, and a prolonged release for continued relief.

The following benefits can be expected from sustained-release papaverine with regard to the forgetfulness, confusion and irritability of cerebral ischemia or the recurrent anginal discomfort of myocardial ischemia:

Pharmacologically, papaverine acts on cardiac and smooth muscle[1,2] including the arterial musculature of cerebral[2] and coronary[3] vessels.

Clinically, papaverine is employed for its vasorelaxant (dilator) action rather than an analgesic in coronary vasospastic conditions[4] and for symptomatic benefit in cerebral ischemia not caused by advanced arteriosclerosis.[5,6]

Sincerely,

A. W. Wilber

"Emphasis on Flow"
VASOSPAN™
(papaverine HCl 150 mg.)
Sustained Release Capsules

Each capsule contains papaverine hydrochloride, 150 mg., in timed disintegration pellets for sustained release. Class M exempt drug. *Indications:* Relief of cerebral and peripheral ischemia associated with arterial spasm, and myocardial ischemia complicated by arrhythmias. *Side Effects:* Rarely nausea, abdominal distress, anorexia, constipation, malaise, drowsiness, vertigo, sweating, headache. *Contraindications:* Use with caution in patients with glaucoma. *Dosage:* 1 capsule every 12 hours. May be increased to 1 capsule every 8 hours.

Subspecialization in Radiology

In the years since the end of World War II, the field of radiology has undergone a complete transformation. The radiologist today is better able to delineate pathology because of improved technology (image intensifiers, television, rapid film changers) and the advent of angiography and other special procedures.

As a result, there has been within this last quarter century a tremendous advancement of knowledge within the field of radiology. The radiologist, generally working in close collaboration with clinical and basic science colleagues, has defined a whole host of radiographic patterns of disease. This burgeoning of knowledge has been due in no small measure to the activities of radiologists who have developed areas of special interest. Generally, such individuals have been working in large academic centers, but by no means is this always the case; radiologists working in community hospitals have contributed much, for example, to the development and improvement of angiography. It is not unreasonable to say that a person interested and engaged in a particular area of radiology becomes more competent in that area than another individual who does or attempts to do the entire gamut of this broad and diverse specialty. In fact, it is probably fair to state that today there can no longer be such a thing as a complete radiologist.[1] Therapeutic radiology is presently in the process of establishing itself as an independent though closely related specialty; such separation is already complete in Canada, Great Britain, and continental Europe. Fairly well defined subspecialty areas of pediatric, neurocardiovascular, gastroenterologic, uro-, and even chest radiology will likely evolve in the next decade. These subspecialties will, of course, only reflect advancement in medical knowledge and practice.

Clinicians trained in medical and surgical specialties in large teaching centers have become accustomed to working with proficient radiologic subspecialists in their areas during residency. Competent radiologic aid and consultation should and can be available to these individuals when they enter private practice.[2] It is to this end that almost every large teaching department of radiology is vigorously pursuing the development of subspecialty training.

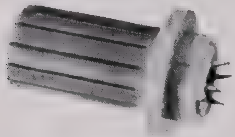
It has been argued that the economics of the private practice of radiology are in conflict with subspecialization. While this may have been true in an earlier era when radiologists practiced solo and the specialty was based more in the office than in the hospital, it is probably much less true today. A large part of radiology today is hospital based, and groups of three or more radiologists in hospital practice are more the rule than the exception. Most of these groups have one or more radiologists with a special competence in the area of angiography. It is not unreasonable to expect that in the near future, individuals with special competence in neuroradiology and pediatric radiology will be found in these groups.

The American Board of Radiology is presently engaged in a study of this trend toward subspecialization.[3] It is likely that the future trainee in diagnostic radiology will receive a core curriculum of approximately two years' length in radiologic basics. Following this, he will take an additional one and one half to two years of subspecialty training. This is not to imply a bleak future for general diagnostic roentgenology; in fact, we can expect that the majority of trainees will opt for and be needed in the practice of the entire field, but that their last two years of training will likely be composed of rotations through the various subspecialty training programs. The greater emphasis on subspecialization will undoubtedly result in better teaching of the general diagnostic radiologist as well as the individual who chooses a special field of competence.

Because of its rich radiologic heritage and the high level of competency of its practicing radiologists, Minnesota is as well prepared as

TB is still around.

In 1967 almost 45,000 new active cases were reported. Isn't that a good reason to make tuberculin testing with the white LEDERTINE™ Applicator a routine part of your physical examinations?



TUBERCULIN TINE TEST

Radiology

THIS ISSUE OF MINNESOTA MEDICINE celebrates the science of radiology in general and extolls one of its brilliant exponents in particular, Dr. Harold O. Peterson, on the occasion of his retirement as Chief of the Department of Radiology at the University of Minnesota. The entire history of radiology in Minnesota is encompassed by the careers of Peterson and his predecessor, Leo Rigler, who as a student witnessed the infancy of the specialty. There are several tributes to Harold Peterson in this issue one of which is from Dr. Rigler; but Rigler's greatest tribute occurred twelve or thirteen years ago when he recommended Peterson to succeed him to the throne of radiology. Today the reasons for that recommendation are apparent to all. The State of Minnesota and particularly its medical citizens are proud of the achievements of Harold Peterson, this native son, who grew to greatness in our midst. He has contributed vastly to the advancement of his specialty; as professor he has taught not only residents numbered in hundreds and students counted in thousands, but the whole world of radiology through his papers and courses. His particular interest in radiology is its application to neurology.

In the era of Rigler and Peterson the great advances in radiology were achieved in part by discoveries of new methods of delineating structure either by opacification or increasing radiolucency, at the same time increasing the source of energy (and other methods), cutting the time of exposure and so culminating in the art of cineradiography. Thus the diagnosis of heart and great vessel disease has been illuminated by angiography. But now the whole methodology of the art of visualizing the hidden organs of the body is in flux. One method produces organ pictures on x-ray film, eliminating the x-ray machine entirely (but not the radiologist!). I refer of course to radioscanning which until recently has been hampered by the cumbersome ox in the field boustrophedonic technic. Employing the Anger camera revolutionizes the method by cutting the exposure time from a large fraction of an hour to a mere fraction of a second.

To hazard a guess about the post-Peterson decade; the seventies should witness great advances in radiology by application of this method. Radiologists have been most ingenious in contorting the human body to line part of it up with an x-ray tube, and a piece of film, so that now half their problem is solved, by rendering that body part temporarily radioactive. A previously impossible view, for instance, a vertical skull picture of the top of the head, will be commonplace. But whatever the advances of the seventies, Harold Peterson will be in the midst of them, for though he is retiring as head of the department of radiology at the University, he is still a young man who will continue to contribute to his field for many years to come. This prediction is well founded in precedent, recognizing what Leo Rigler has continued to accomplish after his retirement.

Old Hospitals

(Continued from page 1872)

The new hospital, completed in 1734, was a one-story brick building, 34 x 90 feet, with a hipped roof in the formal French style of Louis XV. It consisted of a single large room with a fireplace at the far end flanked by windows. Entrances were provided in the center of each of the long sides and at the end adjoining the convent. The floor was tiled and the windows glazed.

The need for room to house "ancillary services" resulted in construction of several additions; the proposed plan for one to include a pharmacy, laboratory and quarters for surgeon and chaplain is shown. By 1752, there were 120 patients in the hospital.

The hospital and its additions were included in the inventory of public buildings of 1766 when Louisiana was transferred to Spain. The Spanish continued to use the facility as a military hospital, and added a second story to the main building. When the United States took possession of Louisiana, the Ursulines acquired title to the hospital, and in 1821 they had it demolished. Today nothing remains of the hospital with the possible exception of part of an old building near present-day Decatur and Governor Nicholls Streets on which can be seen a bit of stucco cornice which may have been part of the old hospital* laboratory.

You May Be Right

Canned Consultation*

Day or night, Monday through Sunday, physicians in this state with a problem patient feel free to and do call consultants of their choice about specific problems. The salutation "Hi" is a warm one for both parties since they have developed a closeness formed of mutual respect due to repeated contacts concerning the welfare of their patients. The closing amenities reflect the same feeling because of shared knowledge and help.

One morning at 2:00 a.m. after finishing the available journals in his hospital staff room with about 20 minutes to wait before his primipara was ready to deliver, the physician dialed 800—356-8103 and updated his knowledge. There was no emergency. Currently there wasn't even a patient with that particular disease in his practice. Which of his consultants should he have awakened with "Hi. Give me a five-minute capsule about . . ."? He avoided wasting his time and he didn't awaken anyone.

Then there was an instance when a physician used Dial Access to check his management of a particular patient. Immediately thereafter he placed a call to his consulting neurosurgeon and this patient was referred for a brain scan and change in management.

The Point? Those physicians who feel Dial Access replaces consultation or even postgraduate study are doing themselves and their patients a disservice. Those physicians who use Dial Access to enhance their knowledge are increasing their ability to care for patients.

Practitioners if you feel federal money should be spent under local control to improve medical care for the population, dial 800—356-8103 and learn something. Consultants, if you feel inclined to share your expertise for the improvement of medical care in Minnesota, dial 612—224-4771 and offer your services.

George B. Martin, M.D.
Thief River Falls, Minnesota

The Minnesota Medicine issue containing your delightful editorial "Canned Consultation"* just landed on my desk. You're right about consultation, of course. It is a human act, not instant information retrieved over the phone from a taped voice. The physician's mind is not a container to be filled with facts, but a synthesizing organ that is best set in motion by talking face to face with a fellow physician. When the powers that be at the Northland Regional Medical Program size up the physician's psyche a little better, perhaps they will make more progress in educating him.

As a start, I suggest they consider the human element. Consultation, like humor, is a human thing. It takes two to interact, and it cannot be classified, categorized, or canned. As E. B. White says in *A Subtreasury of American Humor,* Coward-McCann, 1941, "Humor can be dissected, as a frog can, but the thing dies in the process and the innards are discouraging to any but the pure scientific mind." Minnesota physicians are not yet pure scientists. And consultation, I am confident, will never be an act of pure retrieval.

Richard L. Reece, M.D.
Minneapolis, Minnesota

---

*See Page 1639, October, 1969.

You May Be Right

(Continued)

As a frequent user of Dial Access Medical Library, referred to by the Editor as "canned consultation," I would like to send a few words in its defense. I find it a helpful supplement to consultants, books and journals. One advantage over some journals is that the flow of knowledge is not interrupted by crude suggestions for the use of diet pills, weird drug combinations or reference to the use of vitamin shots for the alleviation of leg cramps.

The Dial Access Library, in its own words, "is a new venture in educational communications." It was originated by the University of Wisconsin Medical School and is designed to provide twenty-four-hour availability to information in abstract form. Many of the authors give their telephone numbers if the user has further questions.

It is my understanding that not one penny of the money you grieve over was allocated to direct medical care because the private sector of medicine fought vigorously to avoid it. If the profession would not react with its usual fear and rigidity to anything federal treading on its sacred ground (but drug company money is fine), perhaps this program might be molded and developed into even greater service.

R. I. Adams, M.D
Minneapolis, Minnesota

Letter to the Editor

"I Goofed"

Bonnie, age four, and I are good friends. We seldom see one another but, when we do, we talk and "catch up" on what's happened since our previous visit.

During our last chat, Bonnie announced "I'm taking violin lessons." When I asked if she would play for me she said simply, "Yes."

She removed her small violin from the case, strung her bow, took her stance with the confidence of a seasoned performer, and began to play. I thought she was doing superbly, but suddenly she stopped and said, "I goofed." After a brief moment's hesitation, she started again and completed her "piece." No excuses, no apology, no evasion, no remorse—just a frank admission! "I goofed."

This refreshing exhibition made me wonder what the world would be like, if we who are older would emulate Bonnie's simple honesty. Suppose we acknowledged our "goofs" instead of resorting to pretense, denial, and projection. Would we feel any better—do any better? Each one of us must answer this question ourselves!

Reynold A. Jensen, M.D.
Minneapolis, Minnesota

President's Letter

The Year 1969

As the year rapidly draws to a close, we are again reminded that many of our problems are still with us, such as the doctor shortage, the lack of sufficient para-medical personnel, Medicare, Medicaid, utilization and review, as well as the high cost of medical care.

Nevertheless, this has been a good year to the extent that we are working on our Medicare and Medicaid problems, and we are in the process of developing a more workable type of utilization review that will be dealt with in a future letter.

It is a pleasure for me on behalf of the officers of the Minnesota State Medical Association, the Council, the Editors of Minnesota Medicine and the Executive Secretary and his staff to extend to all of you greetings and best wishes for a very Merry Christmas and a Happy New Year!

Delmar R. Gillespie

Delmar R. Gillespie, M.D.
President
Minnesota State Medical Association

The Editor's Soliloquy

Carcass Checkers

THERE ARE INDIVIDUALS who awaken in the morning and on arising begin to check their list of signs and symptoms, being insecure in their opinion as to whether or not they are feeling well. Though they suggest to themselves that the doctor who examined them last week found nothing wrong, they are not so sure that he was right. As they raise themselves to the sitting position at the side of their bed, they rub their brow, rotate their neck, extend their joints and feel of their back, at first in fear that they may have—, but a moment later that they may not have—, some signs and symptoms to record in their imagination. These are individuals who love their aches and pains, adroitly exaggerating and embellishing their minor maladies *ad infinitum* and cleverly contriving to inject them into their social and business conversation, as if the horrendous recital of their maladies might hopefully endow them with that extra prestige their egos seem to require. Their prodigious attachment to their chronic functional ailments is phenomenal: to abandon or disavow them would be tantamount to committing treason or heresy. What other animal than the "naked ape" is so resourceful in demonstrating and exploiting its aches and pains to the point of self-martyrdom!

"Oh, my aching bones!" "Why do I have twinges of pain in my legs?" "I cannot sleep a wink." "I lie awake and toss." "Something's got to be done, Doctor."

The aggregate of these and similar complaints constitutes a dissonant but familiar chorus to the physician's ears: a refrain reminiscent of the lamentations of Job. Job's afflictions, however, were visited upon him by an outside agency.*

Obtaining a medical history becomes an almost impossible task because of the numerous interjections of interrelated and very often irrelevant items. Facts can scarcely be distinguished from fancy when these patients insist upon proclaiming their etiology and their diagnosis.

These individuals provide lucrative support to the medical cultists who are happy to accommodate them with an affirmation of their suspicions. A three, four or six weeks course guaranteeing rehabilitation is then prescribed.

Perhaps we should be more appreciative of these individuals for it is they who make it possible for all of us to listen to the "Gee whiz" kids or the "What's your score?" or the "Win a trip" program where, between moments of this type of entertainment, we are promised guaranteed cures as substantiated by "9 out of 10 doctors"; or where one brand of acetylsalicylic acid compound is being proclaimed to be far superior to another because of its bubbling ability to reach the blood stream "fast"; or because it contains the all-powerful FX62 or some other meaningless and mysterious ingredient designed to provide instantaneous social acceptability.

"Except for my sour stomach, my aching head, my halitosis, my hyperhydrosis, my secondary anemia, my chronic insomnia, my tired bowels, my recurring borborygmus, and my irritable disposition, I'd be a well man."

Such is the character of a carcass checker.

Carl O. Rice, M.D.

---

OLD DOC HESS SAYS: Don't talk about your ailments: "How are you!" is expressed with an exclamation point, not a question mark.

Distinguished Service

Harold O. Peterson, M.D.

Professor and Retiring Head
Department of Radiology
University of Minnesota

Dr. Harold O. Peterson

IN THIS issue MINNESOTA MEDICINE is featuring the specialty of roentgenology. No one could better represent in so distinguished a manner the spirit of the true Minnesota physician and the roentgenologist than Harold O. Peterson, retiring chief from the University Department of Radiology. The son of immigrant parents, born in a rural community, educated in one of Minnesota's typical small towns, Harold attained his present eminence by his own extraordinary effort and superior intelligence. In a troubled world in which the ideals, the verities once considered sacred, are being questioned or even abandoned, it is heartening to look back on the career of this unique individual and to revive once more our faith in America's institutions, her opportunities for our young people even of the most humble origins.

The Minnesota sequence of education continued when Doctor Peterson attended the University both as an undergraduate and as a medical student. It is characteristic of his tough realism that he took advantage of his need to earn his way through school by working as a laboratory technician, a splendid occupation for a potential medical student. A year in pathology in the graduate school no doubt gave him the tools needed for his critical approach to radiology. Temporarily, he deviated from this Minnesota pattern by going to the Massachusetts General Hospital for graduate work in radiology. Here he trained under the tutelage of the late Doctor George Holmes, first radiologist in the United States to establish a residency. Here too, he studied with the late Doctor Merrill Sosman, with Doctor Richard Schatzki, and many others then active in radiology in Boston. He returned to Minneapolis to become my first full time associate in the department of radiology at the University, his assignment being neuroradiology.

At its inception as a specialty, radiology encompassed all the medical uses of radiation. This pattern, however, was changing, and the division between diagnosis and therapy had already occurred in the University department. Doctor Peterson elected diagnosis, a wise choice indeed, as later events demonstrated. Roentgen diagnosis, however, was expanding rapidly and subspecialization in neuroradiology, no doubt the most difficult of all its divisions, was already in its incipiency. His intense study of this field, his meticulous attention to detail, and his manual skill all brought him rapidly to the forefront of the group concerned with the application of radiology to neurological diagnosis. He is now considered one of the foremost authorities in the field and has contributed very substantially to the development of this subspecialty.

Nevertheless he has maintained his interest and proficiency in all the ramifications of roentgen diagnosis, contributing substantially to our knowledge of gastrointestinal, urologic and chest diagnosis.

For a time, Doctor Peterson was in private practice, but continued part time at the University. His work was chiefly at the Miller Hospital in St. Paul, where he inspired an extraordinary degree of confidence in his ability, his integrity, and his leadership.

A superb teacher, with a dry and crackling wit, enormously effective because of his deceptively innocent and naive appearance, he has been in great demand as a lecturer and teacher throughout the country. His discussions and demonstrations at the annual meetings of the Academy of Neurology, sometimes running for twelve hours at a stretch, are legendary. He has been in charge of the annual teaching program of the American Roentgen Ray Society and has also carried on and greatly enlarged the traditional annual postgraduate course in radiology at the University of Minnesota. In 1957 he succeeded me as Chairman of the Department of Radiology at the University, and a more worthy choice could not have been made. Since then he has enlarged and expanded the department, which is regarded as one of the finest in America. It is notable that he was elected the first Chief of Staff at the University Hospital. It is well understood that he has had an important role in keeping the medical faculty fully aware of their responsibility to the patient. His outward, sometimes biting humor and his reserved manner actually cover a warm human being with a strong feeling of responsibility to patients—in fact, toward all mankind.

In tribute to his quality and his achievements, Doctor Peterson has received the highest honors which his colleagues in radiology could confer: President of the American Roentgen Ray Society; President of the American Board of Radiology; Chancellor of the American College of Radiology, and numerous other offices.

The whole career of this distinguished son of Minnesota has been characterized by a determined truthfulness and a complete devotion to the ideals and best practices of American medicine. Coupled with a highly critical sense of his own limitations and those of radiology is his desire for perfection which has limited his contributions. Nevertheless, Doctor Peterson has won an everlasting niche in the annals of medicine in the United States.

He is a deeply religious man, as is also his lovely and helpful wife, Margaret. Together they have brought up a fine family. Both have met good fortune and adversity with rare faith and equanimity, and together have achieved a respected and affectionate place in the hearts of their fellow Minnesotans. He will soon give up the onerous administrative duties as Chairman of his department, but will continue to contribute to Minnesota, to the United States, in fact, to the world, his knowledge, his skills and his inspired teaching. His strong spirit will still move forward, striving for further knowledge and perfection. All of his students and many friends and admiring colleagues wish him and his beloved wife many more fruitful years with happiness and contentment.

Leo G. Rigler, M.D.
Los Angeles, California

---

*University of California.

Success

Someone made a survey of 1,000 successful men to learn how they got their start in life. They were not mere money-makers but were men who made the world better by their work.

Three hundred started as farmers' sons; 200 started as newsboys; 100 were printers' apprentices; 100 began in factories; 50 began at the bottom of railroad work. Fifty, only 50, had wealthy parents to give them a start!

Brickwork.

The man who says it can't be done is interrupted by the man who is doing it—Jacob Braude: Speaker's Encyclopedia

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol. An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take. PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Parke, Davis & Company
Detroit, Michigan 48232

Appearances may be deceiving

It may be tetracycline

but it's not ACHROMYCIN® V

Tetracycline HCl

unless it bears this signature.

Lederle
Lederle

250 mg. and 100 mg. capsules

Contraindications: Hypersensitivity to tetracyclines. *Warning:* In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs. *Precautions:* Nonsusceptible organisms may overgrow; treat superinfection appropriately. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Side Effects: Gastrointestinal—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity reactions*—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

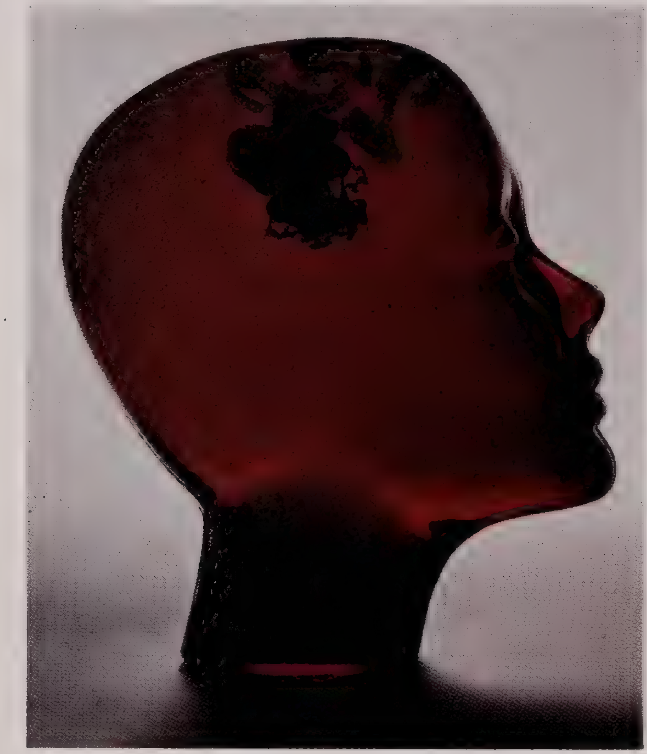
Even mild to moderate anxiety is often tinged with depression



Anxiety, even mild anxiety, seldom exists alone. Often it is mixed with depression, not necessarily of obvious and overwhelming proportions, but meaningful all the same in its effects on the patient.

In mild to moderate anxiety, consider the therapeutic edge you get with Mellaril 10 mg. t.i.d. This dosage is not only well suited to control mild to moderate anxiety, but it is also effective against the depression which might be present.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

(thioridazine)
10 mg. t.i.d.

for mild to moderate anxiety and anxiety with depression

The Viewing Box

Renal Mass

THE PATIENT is a 69-year-old white female who was admitted to the hospital for evaluation of vague and long-standing gastrointestinal complaints. There were no symptoms or clinical findings referable to the genitourinary system. Routine laboratory studies showed no significant abnormality; urinalysis was normal. Radiographic examination of the gastrointestinal tract disclosed diverticulosis of the colon; but no other findings were encountered. An intravenous pyelogram was performed which demonstrated a four-by-six centimeter mass density along the lower, lateral margin of the left kidney although there was no distortion of the upper collecting system. These findings were confirmed by nephrotomography. Selective renal arteriography was then performed. Representative radiographs obtained in the course of this study are reproduced below (Figures 1 and 2). The patient then underwent a left nephrectomy.

What is your diagnosis? (See next page).

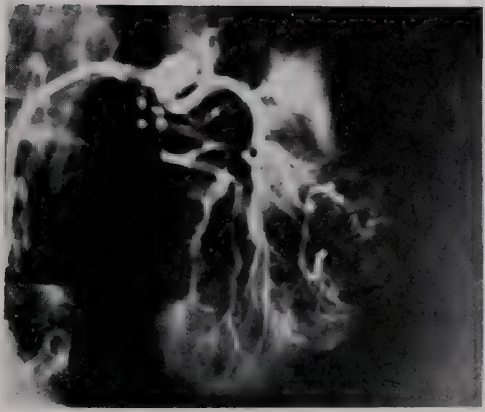

Figure 1

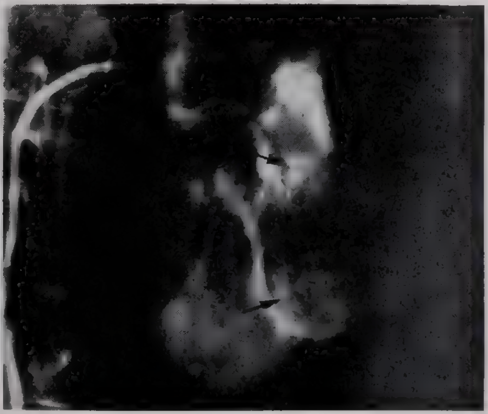

Figure 2

Diagnosis: Hypernephroma

The angiogram discloses evidence of neovascularization (arrows shown in Figure 1) and puddling of contrast medium (arrows, Figure 2) in the region of the tumor. On the basis of this examination, a diagnosis of hypernephroma was made and a nephrectomy performed. Gross pathological examination of the lesion appeared to confirm this diagnosis. Microscopic sections, however, revealed a rather mixed histologic pattern with areas of smooth muscle, lobules of adult adipose tissue and areas of an angiomatous appearance. Occasional organoid-appearing structures were encountered. The final pathologic diagnosis was angiomyolipoma of the left kidney.

In spite of the ominous appearance obtained at arteriography, the angiomyolipoma is a benign lesion classed as a hamartoma.[1] It is a relatively rare, but well-recognized, tumor which may occur in two types. In one type it is associated with tuberous sclerosis. In this instance, there are bilateral lesions which are multifocal and equally distributed between the sexes in young persons. The second type, which is exemplified in this case, is unilateral, solitary and most commonly occurs in females during the sixth or seventh decade of life. Presenting complaints are often flank pain or hematuria. Massive retroperitoneal hemorrhage may occur due to rupture of the lesion and a palpable mass may be present.[1] The patient may, as did this lady, present with nonspecific gastrointestinal complaints.[2,3]

Although renal angiography is of great value in the differentiation of benign and malignant mass lesions of the kidney, this case demonstrates that a benign lesion can, rarely, closely mimic the findings of a malignant hypernephroma.

Early Conditioning

My first memory dates back to an incident that happened when I was four years old. I was walking with my elder sister, Sabina, pulling a little wagon in which rode the baby—my brother Philip. We were menaced by a drunkard, and we ran shrieking—my sister and I—pulling the wagon until we reached our home. Since then I have always feared drunken people, whose actions and conduct are unpredictable; and I have abominated drunkenness. Sometimes at banquets I have sat next to people who have been pouring in highballs—manhattans and triple martinis. They shout, they laugh, they emphasize their remarks by poking me and punching me—and I used to bruise easily. By such nuisances an evening has been ruined.*

False Positive Serology

PROBLEMS CAN BE encountered in the interpretation of serologic tests for syphilis. A particularly vexing situation is the false positive reactor: a serologic state characterized by repeatedly reactive nontreponemal tests while the treponemal* tests remain nonreactive.

The occurrence of a false positive reaction is due partly to the nature of the test employed. Nontreponemal or reagin tests use cardio-lipin-lecithin as a nonspecific antigen, examples of which are the Kolmer complement fixation and Venereal Disease Research Laboratory slide flocculation tests. Reagin measured by these tests is elevated in primary syphilis four to six weeks after infection. However, reagin is not specific for syphilis but may be present in measurable amounts as a consequence of several medical conditions. Herein arises the problem of one type of false positive reactor. These reactions can be acute (less than six months' duration) or chronic (six months or longer).

Acute Reactions

Acute false positive reactions may occur following bacterial and viral infections, including vaccinations; also very high reagin titres have been recorded following infectious mononucleosis. At other times no history of prior infection or immunization is obtainable. Most often in this situation the titres are low and revert to normal within two months.

Chronic Reactions

Chronic false positive reactions are less common than the acute type. Systemic lupus erythematosus and other so-called auto-immune diseases may be associated with this condition. Yaws, pinta, and bejel frequently show positive reagin titres. This agrees with the unitarian concept that these treponematoses are merely variants of syphilis. Lepromatous leprosy, lymphogranuloma venereum, malaria, and heroin addiction have also been associated with false reactivity based upon reaginemia. Of course, the presence of these diseases does not preclude the occurrence of syphilis, a fact which can complicate diagnosis in certain situations.

There is one more type of false reaction—that of a technical nature. All normal sera may contain very small amounts of reagin. The sensitive nontreponemal tests may become even more sensitive if some of the physiochemical variables in their performance are altered. This can result in low titres being reported. About one fourth of all false positive reactions are due to such technical errors. Repeat testing discloses such a situation. Finally it should be mentioned that clerical error can occur and repeat testing is desirable before any patient is treated.

With the advent of the treponemal tests the problem of the false reaction has become somewhat less confusing. Treponemal tests are characterized by less sensitivity and greater specificity than the nontreponemal procedures. These tests use as the antigen either the protein fraction of the nonpathogenic Reiter treponeme or T. pallidum itself (viable or dead). Two of these tests are of special interest here: the Treponema Pallidum Immobilization and the Fluorescent Treponemal Antibody tests.

---

*See Test Your Word Score Page 1921.

The Treponema Pallidum Immobilization test was developed first and is time-consuming as well as technically difficult and therefore costly to perform. However, until the Fluorescent Treponemal Antibody test, it was probably the chief means of differentiating the false reactor.

Differentiation

Recently the Fluorescent Treponemal Antibody test has gained favor in differentiating false positive reactions. This test uses dead T. pallidum on a microscope slide, overlaid with the patient's serum. If antibody to T. pallidum is present, this adheres and can be detected using fluorescein-labeled antihuman gamma globulin: essentially the indirect Coons' fluorescent technique. Today this test has been further refined by absorbing the serum with an extract of nonpathogenic treponemes, thus removing the treponemal "group" antibodies while specific antibodies to T. pallidum remain. This is referred to as the Fluorescent Treponemal Antibody Absorption Test.

Recent studies have demonstrated that the Fluorescent Treponemal Antibody Absorption procedure is probably the most sensitive treponemal test. Also, it is the test of choice in differentiating false positive reactors from syphilis.

In conclusion, it must be pointed out that all tests are subject to error and should not replace clinical judgment.

IT'S THE LAW

Physician's Bills Recoverable in Personal Injury Suit

A 17-year-old girl sustained severe facial injuries which required extensive plastic surgery. She was the daughter of a physician. Because of the accident, she became anxious and depressed, necessitating psychiatric treatment.

The negligent driver contended that the plastic surgeon's and the psychiatrist's bills should not be included as items of damages because the girl's father was a physician, and professional services had been rendered as a matter of professional courtesy.

The court ruled that the value of the physician's services, as well as hospital and medical bills incurred by a person injured, can be recovered even though such services are rendered gratuitously. The bills of both the psychiatrist and plastic surgeon were ordered to be paid.

is not a harmless privilege" —Current Therapy 1967, ed. by Conn, H. F., P. 88—

if cough serves no useful purpose

Rx **Tussionex**®

(Resin complexes of Hydrocodone and Phenyltoloxamine)

...it works (usually for 10 to 12 hours*)

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic – oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.

*DOSAGE: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

Anxiety is expected in the cardiovascular patient. A little may even be desirable.

But when anxiety is exaggerated . . . when it interferes with sleep . . . when it aggravates cardiovascular symptoms, your help may be needed.

Naturally, you'll want to reassure the patient.

And perhaps prescribe Equanil (meprobamate) as adjunctive therapy. It helps relieve anxiety and tension specifically, yet gently.

Almost 15 years' use has shown that Equanil is usually well tolerated as well as effective. Side effects are generally limited to transient drowsiness; serious, therapy-interrupting side effects are rare.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

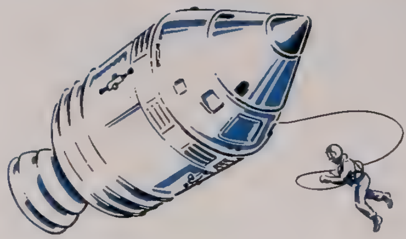
Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Wyeth Laboratories Philadelphia, Pa.

Equanil®

(meprobamate) Wyeth®



Man in space, now fait accompli, re-emphasizes the importance of Uro-Phosphate therapy. Research into the effect of space travel on the astronaut reveals that weightlessness causes loss of bone calcium. As the bones are required to bear less and less of the weight of the body they lose calcium, increasing the calcium content of the urine. When physical activity is reduced, the acidity of the urine should be adjusted to keep increased calcium in solution . . . . a prophylaxis to prevent kidney or bladder calculi.

Uro-Phosphate®

NOW A SUGAR-COATED TABLET

Each tablet contains: METHENAMINE, *300 mg.;* SODIUM ACID PHOSPHATE, *500 mg.*

Uro-Phosphate gives comfort and protection when inactivity causes discomfort in the urinary function. It keeps calcium in solution, preventing calculi; it maintains clear, acid, sterile urine; it encourages complete voiding and lessens frequency when residual urine is present.

Uro-Phosphate contains sodium acid phosphate, a natural urinary acidifier. This component is fortified with methenamine which is inert until it reaches the acid urinary bladder. In this environment it releases a mild antiseptic keeping the urine sterile.

Uro-Phosphate is safe for continuous use. There are no contra-indications other than acidosis. It can be given in sufficient amount to keep the urine clear, acid and sterile. A heavy sugar coating protects its potency.

Dosage:

For protection of the inactive patient 1 or 2 tablets every 4 to 6 hours is usually sufficient to keep the urine clear, acid and sterile.

2 tablets on retiring will keep residual urine acid and sterile, contributing to comfort and rest.

A clinical supply will be sent to physicians and hospitals on request.

Carcinoma of the Prostate

The Rationale of Therapy

As for any neoplasm, the rationale of therapy in carcinoma of the prostate depends on the evaluation of three basic factors: (1) the risk of the untreated tumor, (2) the potential risks and benefits of the proposed therapy, and (3) the comparative potential risks and benefits of the therapeutic alternatives. The evaluation of these three basic factors depends on a knowledge of the pathology and natural history of prostatic carcinoma and of the results achieved by each therapeutic modality. Recent advances in these areas have created a state of flux.

Recent Advances

The Role of the Lymphatics

One of the most important advancements in the basic pathology of prostatic carcinoma is the recognition of the role of the lymphatic vessels in the dissemination of the disease. Lymphangiography has shown a distribution of lymphatic vessels pursuing a course similar to that of the vertebral plexus of veins and, importantly, has shown direct communications between the lymphatic vessels and the veins of the pelvis.[1]

The Lymph Nodes

Regional metastasis of cancer of the prostate is most often to the external iliac, hypogastric, and sacral nodes.[2] From these regional nodes the cancer may metastasize to the periaortic nodes and occasionally to the cervical and supraclavicular nodes. The inguinal nodes are rarely involved.

It has been emphasized that advanced prostatic cancer (by clinical appraisal) need not be present for nodes to be metastatically involved. Arduino and Glucksman[3] reported 71 patients in whom clinical appraisal revealed cancer limited to the prostate and who underwent radical prostatectomy. About 27% had metastatically involved pelvic lymph nodes. Microscopic evidence of involvement of the prostatic capsule without actual perforation was not associated with an increased incidence of nodal metastasis (7% nodal metastasis). However, microscopic invasion of the seminal vesicles was associated with an 82% incidence of pelvic nodal metastasis. These authors believed that, when local extension of the tumor beyond the prostate is evident clinically, the incidence of pelvic lymph node metastasis approaches 100%.

Hematogenous Dissemination

It has been postulated that cancer cells are diverted by lymph node metastasis from their usual lymphatic channels and are carried through the alternate lymphatic vessels, investing the bony pelvis and vertebrae, together with the vertebral plexus of veins.[1] It is important to recall that there is free communication between the pelvic veins and the vertebral plexus of veins,[4,5] and that early hematogenous dissemination is possible in this disease.

Perineural Involvement

Perineural involvement with carcinoma, formerly believed to be in perineural lymphatic vessels, is now known to be in perineural spaces. This finding is pathognomonic of carcinoma and is helpful in differentiating low-grade carcinoma from adenoma, but occurs in 80 to 90% of all carcinomas and is prognostically meaningless.[6,7]

For many years it has been recognized that prostatic cancer is usually multicentric in origin and may begin in any one or several of the five lobes of the prostate. This belief is opposed to the earlier one in which the cancers arose from a single focus almost always in the posterior lobe. The carcinomas are also known to arise in most cases in the periphery of the prostate in a subcapsular position far removed from the prostatic urethra. Obstructive symptoms are, therefore, unusual in the early phase.

Cellular Differentiation and Clinical Staging

Another important investigation in the basic pathology of prostatic carcinoma has been an attempt to relate prognosis with systems of classification that incorporate a combination of cell differentiation and histologic pattern with and without clinical staging.[8-10] Utz and Farrow[11] found that the histologic grade of prostatic cancer is the most valuable guide to the growth rate of the tumor and survival of the patient, but that clinical staging of the cancer based on symptomatic manifestations, digital rectal evaluation of extension, and laboratory or roentgenographic evidence of distant metastasis must be considered in the total profile of this diverse tumor. Although these authors believe that the combined clinicopathologic evaluation will greatly improve the accuracy of prognostication, they expect forthcoming help from current research in prostatic enzymology and histochemistry.

Clinical Staging

Proper staging of prostatic carcinoma is as important as cellular differentiation in the selection of treatment and enables comparisons of different forms of therapy. The World Health Organization clinical staging system divides all prostatic cancers into four stages based on the results of rectal examination, roentgenographic studies of the skeleton, prostatic or total serum acid phosphatase determinations, and biopsy from the prostate (Table 1).

At the Mayo Clinic, the staging system incorporates more tests of metastatic involvement (Table 2), but in this discussion the staging system of the World Health Organization will be used because most of the literature currently available employs that system.

Natural History of Untreated Prostatic Carcinoma

Stage I—"Untreated"

Comparisons between the incidence of stage I carcinoma of the prostate found incidentally at autopsy or surgery and the mortality rate of patients with stage III or IV prostatic cancer reveal a large discrepancy. The natural history of most stage I carcinomas of the prostate is sufficiently long to allow the patient to die of other causes.[13]

In stage I or occult cancer of the prostate, the operative procedure that led to the discovery of the cancer may alter the natural course of the disease. Greene and Simon[14] reported six cases in which the diagnosis of occult carcinoma was made on the basis of transurethral resection specimens but in which subsequent specimens taken during transurethral resection or suprapubic prostatectomy failed to show carcinoma. Likewise, in 14 patients in whom occult carcinoma was found, subsequent radical prostatectomy failed to reveal cancer in five.[15] These and other reports confirm that occult carcinoma occasionally can be eliminated by conservative prostatectomy (simple perineal, suprapubic, retropubic, or transurethral). Thus there is no such patient as one with "truly untreated" stage I prostatic cancer. Nevertheless, this is the type of patient that can be considered in this group.

The study by Bauer and associates[16] has shown that the survival rates in microscopically well-differentiated lesions was 75% at five years and 47% at 10 years. Poorly differentiated lesions are associated with survival rates of 33% (24 patients) and 14% (seven patients) at five and 10 years respectively.

Greene and Simon,[14] using material from transurethral resection specimens, found overall survival rates of 70.7 and 39.4% at five and 10 years, respectively. These survival rates are 95 and 85% of the normal actuarial survival rates for patients of the same age without cancer. Most studies confirm these figures.

Melicow[17] believes that latent prostatic carcinoma in the elderly patient tends to have a low lethal potentiality, whereas in the younger patient this type of cancer is highly invasive locally and early metastatic spread is likely. Bailar and associates,[18] however, believe that a prostatic carcinoma of any given histologic grade is no more malignant in a young person than in an elderly patient.

The bulk of the present information indicates that prognosis in stage I prostatic cancer is dependent to some extent on the histologic grade of the lesion but that most men with stage I carcinoma will die with their disease rather than of it.

Stage II—"Untreated"

Andersen[19] reported two five-year and one 10-year survivor among 11 patients who had received no treatment. Cook[20] reported a 10-year survival rate of 24% in 25 cases.

The natural history of some stage II lesions must be long, as evidenced by local recurrence or metastasis after apparent cancer-free periods of five, 10, or even 15 years. However, it is obvious from the survival rates of patients with stage II cancer who have been treated that it is a potentially lethal tumor with an approximate mortality rate of not less than 50% in five years if left untreated.[13]

In the paper by Shelley and associates[8] previously mentioned, most patients who were suitable for radical prostatectomy (those with stage I or II lesions clinically) had histologically higher grade tumors. In Culp's[21] series of 123 patients selected for radical prostatectomy, 113 had histologic grade I or II lesions. The poor prognosis of the unusual (four of 92 cases) undifferentiated carcinoma in a clinically stage II lesion, even with treatment, was also borne out in the recent series by Jewett and associates.[22] All four of his patients died.

From our present knowledge, the indication is that the natural history of stage II carcinoma of the prostate varies with the histologic differentiation of the cancer. It should be emphasized, however, that among the histologically well differentiated lesions, differences in grading are not a good basis for prognostica-

TABLE 1

World Health Organization Staging System for Pathologic Proof of Prostatic Cancer

Stage	Rectal examination	Acid phosphatase	Bone survey	Percentage of all patients presenting with prostatic cancer[12]
I	Findings negative	Normal	Negative	5
II	Localized nodule	Normal	Negative	8
III	Extraprostatic extension	Normal	Negative	48
IV	Findings may vary	Elevated or	Positive	39

TABLE 2

Mayo Clinic Staging System for Pathologic Proof of Prostatic Cancer

Stage	Rectal examination	Acid phosphatase	Bone survey	Bone scan	Bone marrow
0	Findings negative	Normal tartrate inhibited fraction; total may be slightly elevated	Negative	Negative	Negative
I	Localized nodule (<1.5-cm diameter)	Same as above	Negative	Negative	Negative
II	Localized nodule (>1.5-cm diameter)	Same as above	Negative	Negative	Negative
III	Extraprostatic extension	May be elevated	Negative	Negative	Negative
IV	Findings may vary	Elevated (with one of the following positive)	Positive	Positive	Positive

tion in an individual case. In this group, the latent and the lethal lesions look alike.

Stage III—"Untreated"

Untreated stage III carcinoma of the prostate appears to have a more uniformly lethal potential. A number of large series have noted that survival rates ranged from 5 to 15% for five years and averaged about 5% for 10 years. However, many of these series overlap into the "preacid-phosphatase era", and undisclosed numbers of the patients had no bone surveys, so that many of these patients would now have been grouped with patients who had stage IV lesions. Thus these figures may be low.

A recent study by the Veterans Administration research group,[12] of 2,057 prostatic cancer patients, including 983 with stage III lesions, revealed a startlingly high five-year survival rate of 57% for untreated patients.

Preliminary reports[8] indicate a relatively high incidence of histologically undifferentiated carcinomas in stages III and IV and a rather low incidence of differentiated or grade I tumors. However, there is no completed study of the variation of survival with histologic grade in stage III untreated carcinomas of the prostate.

Stage IV—"Untreated"

Stage IV or metastatic carcinoma of the prostate is associated with a grim prognosis. Patients with untreated stage IV disease have a five-year survival rate of between 0 and 20%.[12] The average survival of untreated patients with stage IV disease is about one year.

The Risks of Therapy

The two more commonly used treatment modalities are surgery and antiandrogenic therapy.

Surgery

According to Whitmore[13] the following ablative procedures might be logically considered in the surgical attempt to eradicate prostatic cancer: (1) radical prostatectomy (either perineal or retropubic approach), (2) radical prostatectomy with regional lymph node dissection, (3) prostatectomy and simple total cystectomy, (4) prostatectomy and radical cystectomy, and (5) pelvic exenteration.

The operative mortality rates from these ablative surgical procedures range from 1 to 5% with radical prostatectomy, through 10 to 15% for simple or radical cystectomy, to about 20% with pelvic exenteration.

All these procedures will almost invariably lead to loss of sexual function. Radical prostatectomy carries a risk of urinary incontinence. Cystectomy necessitates the hazards and inconveniences of urinary diversion and, in the case of pelvic exenteration, a colostomy as well.[13]

Antiandrogenic

Since 1941, when Herbst[23] and Huggins and Hodges[24] reported the first of many experiences with the antiandrogenic therapy of prostatic cancer, various estrogens have been used. Most are synthetic. Diethylstilbestrol is the most commonly used.

Although it is the best drug therapy for prostatic cancer, estrogen therapy is not innocuous, contrary to prevailing opinion. It causes embarrassing and often painful gynecomastia, changes in the skin and fat distribution, testicular atrophy, and decrease in or loss of libido. It may also interfere with obtaining a positive tissue diagnosis by biopsy in the future.

An even more important controversy is that some estrogens may decrease the patient's life expectancy, primarily by increasing the incidence of cardiovascular complications.[12] Significantly, a recent study by Hanash and coworkers[25] has shown that there was not an increase in coronary artery or aortic atherosclerosis in estrogen-treated prostatic cancer patients, but that estrogens did increase the risk of congestive heart failure.

Orchiectomy, which has a low associated operative morbidity and a low mortality rate, has perhaps its greatest risk in the psychologic effects it causes.

The Results of Therapy

Stage I—Subtotal Prostatectomy

Bauer and associates[16] have shown a decreased survival rate in the unusual patients with stage I prostatic cancer that is histologically poorly differentiated. More often the patient with low-grade stage I cancer has a favorable prognosis (Table 3).

Greene and Simon[14] noted a five-year survival rate of about 71% for their patients who had transurethral resection only. Montgomery and associates[27] studied 35 patients who had had stage I carcinoma for at least eight years. At the time of their report no patient had died of prostatic cancer. Labess[26] traced 33 patients who had had stage I carcinoma treated by suprapubic enucleation and found that 85% lived five years or more.

Subtotal prostatectomy plus antiandrogenic therapy in stage I cancer do not reveal a favorable effect on survival. In Greene and Simon's[14] series the five-year survival of patients treated by transurethral resection plus diethylstilbestrol was 67%, as opposed to about 71% for patients treated by transurethral resection alone.

TABLE 3

Survival After Therapy for Stage I Prostatic Cancer

	Survival, %

†Poorly differentiated lesions.

‡Nodule less than 1.5 cm.

In the series of patients with occult carcinomas reported by Bauer and co-workers,[16] no demonstrable increases were seen in the survival rates for patients who received estrogens or who underwent castration. This observation applied to patients with well-differentiated lesions as well as to those with poorly differentiated lesions.

Stage I—Radical Prostatectomy

The most recently published large series of patients with stage I carcinomas treated by radical prostatectomy is that of the 161 patients in the Veterans Administration group study.[12] Of these, only one patient died of prostatic cancer during the five-year period reported.

Stage II (Table 4)—Radical Prostatectomy

The prognosis is affected by the histologic grade of the lesion. Because the staging system is a clinical one, the percentage of patients with disease limited to the prostate (as proved by examination of the surgical specimen) in any given series will greatly affect the survival statistics of that series.

Survival curves reported by Jewett and associates[22] over a 15-year period (Table 5) were in close agreement with those of Turner and Belt,[29] who reported a 43% 10-year survival rate after radical perineal prostatectomy.

Leadbetter and associates[30] also confirmed the influence of histologic grade on survival after radical prostatectomy by their report of overall five- and 10-year survival rates of more than 70% and of 40% as compared to 50% and 12% for patients with poorly differentiated tumors.

In a series of patients with localized nodules less than 1.5 cm in diameter, Culp[21] noted a 10-year survival rate of 71%. In larger lesions confined to the prostate, the 10-year survival was 54%. In his series Culp found that patients with grade I lesions had a 50% better chance of 10-year survival than did those with comparable grade II cancers.

Stage II—Antiandrogenic Therapy

Jewett[32] in 1963 reported an extended study of 40 patients with stage II cancer who were followed for 15 years or more after radical perineal prostatectomy. All had microscopic confirmation of cancer limited to the prostate; the survival rate at 15 years was 30%.

In *22* comparable patients with stage II lesions (but without microscopic confirmation of limitation to the prostate) treated by Barnes[33] with endocrine therapy alone, the survival rate was 32% at 15 years.

Andersen[19] reported five and 10-year survival rates of patients with stage II cancer treated with endocrine therapy as 65 and 35%, respectively.

The recent Veterans Administration study group series,[12] although of limited comparative value because of only a five-year follow-up and because they have considered stage I and stage II cancers together in their reporting, may be useful for comparison of survival rates of radical prostatectomy alone versus radical prostatectomy plus estrogen therapy. According to that report the detrimental effect of estrogens on the survival rate was considered statistically significant and produced a 10% decrease in survival rate (from 85 to 75% five-year survival). However, many authorities believe that if a high-grade lesion is found at operation or if extension beyond the prostatic capsule is discovered on review of the microscopic section or if both are noted, antiandrogenic therapy should be initiated immediately.

Stage III—Radical Prostatectomy

Radical prostatectomy is rarely done in the presence of clinical extension beyond the prostate because of its limited value. However, a number of investigators have studied the results in patients who were believed to have stage II cancers, who underwent prostatectomy, and who were found to have extension beyond the capsule of the prostate. Jewett[28] reported a 10-year survival rate of 23% for such patients and 12.5% for those with clinical stage III disease. Turner and Belt[29] reported five- and 10-year survival rates of 47 and 25%, respectively, for patients with stage III cancer treated by radical prostatectomy; but they may have had several patients with stage II lesions in their series.

Whitmore and Mackenzie[34] reported that none of the 17 patients with stage III cancer who were treated by either radical cystectomy or pelvic exenteration were cured.

Stage III—Antiandrogenic Therapy

The experience with antiandrogenic therapy in stage III prostatic carcinomas is summarized in Table 6. According to Emmett and co-workers,[10] orchiectomy achieved the best results when done before metastasis appeared and diethylstilbestrol did not seem to improve survival statistics.

Although all these reported survival rates are about the same, the recent study by the Veterans Administration group has raised some issues about the estrogen treatment of prostatic cancer. Figures in that study indicate that although estrogen-treated patients have a decreased mortality rate from prostatic cancer the mortality rate from cardiovascular complications is increased.

In stage III lesions, a combination of endocrine therapy followed by surgery was employed by Scott.[39] In a series of 31 patients selected because of their responsiveness to endocrine therapy, a 10-year survival rate of 61% after radical perineal prostatectomy was observed.

TABLE 5

Fifteen-Year Survival Rates in Prostatic Cancer

Criterion	Survival, %
Grade of histologic differentiation	
Grade 1	28
Grade 2	32
Grade 3	0
Extent of local spread*	
Confirmed intracapsular	40.7
Confirmed extracapsular	5.9

*As determined by microscopic examination of surgical specimen. Overall survival rate according to extent of spread was 35%. (Modified from Jewett, H. J., Bridge, R. W., Gray, G. F., Jr., and Shelley, W. M.: The Palpable Nodule of Prostatic Cancer: Results 15 Years After Radical Excision. JAMA 203: 403, 1968.)

Turner and Belt[29]	47	25	Radical prostatectomy
Jewett[28,32]		12.5	Radical prostatectomy

Stage IV—Antiandrogenic Therapy

No direct surgical therapy is possible for clinically metastatic or stage IV cancer of the prostate. The most often used therapy is antiandrogenic. Orchiectomy is the best palliative therapy. When the cancer becomes resistant to one type of estrogen, alternation of estrogen preparations may induce a symptomatic remission. Diethylstilbestrol diphosphate has been shown to be potentially useful.[40]

Additional forms of hormonal manipulation include (1) the exogenous administration of corticosteroids, (2) bilateral adrenalectomy, (3) ablation of the pituitary gland either surgically or by irradiation, and (4) progestational agents.[41]

Stage IV—Radiation Therapy

External-beam irradiation of painful skeletal metastasis has provided a significant palliative effect in a large percentage of patients. The tumor dose delivered to a particular metastatic site in bone usually varies from 1,200 to 2,500 rads.

An additional method of relieving bone pain from prostatic cancer metastasis is systemic irradiation with radioactive phosphorus, ^{32}P, a beta-emitter with a half-life of 14.3 days. The uptake of ^{32}P in the osteoblastic metastasis is said to be increased 15 to 20 times by the administration of male hormones.[42] Thus ^{32}P is usually given during a course of testosterone. Recently Kaplan and associates[43] have noted favorable results in metastatic prostate cancer, using polymetaphosphate labeled with ^{32}P.

Radiotherapy for Cure

Historically, radiation therapy has been considered important in the palliative treatment of prostatic cancer. However, the challenging role of radiotherapy is that of primary treatment with curative intent.

In the past there have been varied attempts to cure prostatic carcinoma by employing ionizing radiation. The interstitial irradiation techniques with radon seeds or radium needles often failed, presumably because of their inability to achieve homogeneous dosage distribution within the tumor. An additional factor of concern was the tissue toxicity of the high dose, since the radiation was delivered in a necessarily short time.

Orthovoltage Irradiation

The scope of orthovoltage irradiation as an adjunct to interstitial therapy was limited. External irradiation with orthovoltage equipment produced severe skin reactions involving the perineum, genitalia, and anus when efforts were made to deliver a significant dose to the prostate.

In 1951 Flocks[44] introduced the technique of interstitial injection of radioactive gold into the prostate and seminal vesicles. Various anatomic approaches were used. In selected patients treated by Flocks and a few others experienced in this technique, favorable results were accomplished. These results have proved to the satisfaction of many the ability of radiation to destroy adenocarcinoma of the prostate. The procedure has the same disadvantages that other forms of interstitial irradiation have, that is, the inability to achieve a sustained and evenly distributed irradiation of the tumor.[45]

Supervoltage Radiotherapy

Within the past few years, supervoltage radiotherapy has been employed with curative intent in patients with prostatic carcinoma confined to the pelvis; but to date there are only a few reports in the literature on this subject. In 1965 Bagshaw, Kaplan, and Sagerman[46] reported the use of x-rays produced with a 4.7-Mev linear accelerator in the treatment of 81 patients with prostatic carcinoma. Also in 1965, George and associates[47] reported using cobalt-60 teletherapy to treat nine patients. Del Regato[45] in 1967 reported using cobalt-60 teletherapy in seven patients with prostatic cancer, and in 1968 Bennett[48] reported cobalt-60 teletherapy in 11 patients.

Patient Selection

The method of patient selection*, although not specifically stated in several of these preliminary reports, seems to follow that of Bagshaw and associates:[46] (1) the patient must have carcinoma proved by biopsy, (2) the carcinoma should be localized to the region of the prostate, its capsule, or the immediate periprostatic tissue, with no hematogenous metastasis, and (3) either the cancer must be too extensive for radical prostatectomy or the patient must have refused surgery.

Interestingly, both Bagshaw and George advocate treatment in the presence of an elevated level of acid phosphatase if the bone survey is negative. Most of the recent literature has stated that if the level of acid phosphatase is elevated, the patient is considered to have stage IV or metastatic cancer. Recent knowledge of the frequency of lymph node involvement in clinical stage III disease makes it difficult to meet the second criterion of patient selection, previously listed. Perhaps lymphangiography will help in this regard.

---

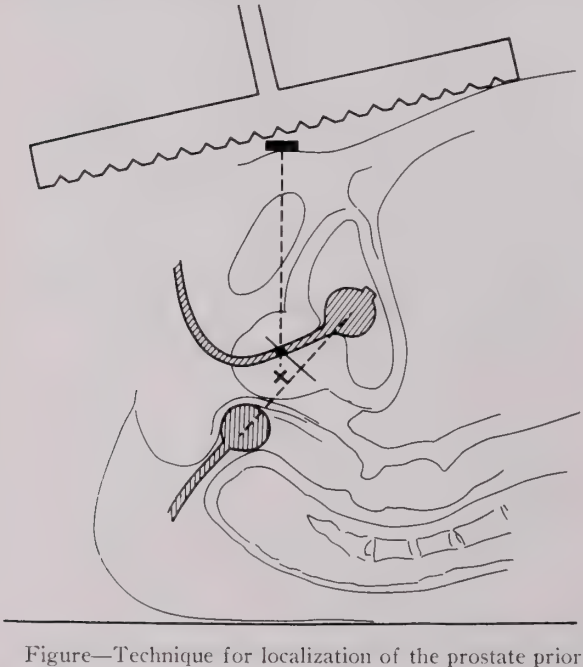
*Schirmer and Scott[49] believed that the rationale for irradiation in prostatic cancer should be based on differentiation and catalase activity of the cancer cells. They postulated that irradiation destroys prostatic cancer because of a combination of hydrogen peroxide formation and decreasing catalase activity, the latter found with increasing dedifferentiation of prostatic cancer cells.

Treatment Planning and Delivery Techniques

Treatment planning techniques vary among reporting institutions. Like those in other institutions who use either rotational or cross-firing methods, our group at the Mayo Clinic employs confirmatory localization films of the treatment area. The current method (Figure) consists of placing a mark with ink on the patient's skin over the center of the symphysis pubis in the midline. The patient then goes to the urology subsection of the diagnostic radiology department where a lead marker is placed over the ink mark and taped in place, a Foley catheter is inserted into the urinary bladder, and the balloon, filled with contrast medium (69% Renovist), is pulled down firmly against the prostate. Next, a catheter is inserted into the rectum, the balloon is filled with Renovist, and an across-the-table lateral roentgenogram is taken, with the central axis being at the level of the lead marker and with a distortion scale placed in the midline. The superior and posterior surfaces of the prostate gland are delineated by the contrast medium in the catheter balloon and rectum, respectively, while the urethra is demonstrated by the medium in the lumen of the catheter. The center of the prostate gland is judged to be 1 cm posterior to the prostatic urethra.

The roentgenographically localized center of the prostate gland is then related to the skin marker, and the distance from the skin to the center of the prostate is measured, with correction being made for magnification (as indicated by the distortion scale).

Although several different techniques have been employed in the past five years in delivering high-dose external radiation therapy to the prostate, the technique most commonly used at the Mayo Clinic employs the 6.3-Mev linear accelerator and multiple cross-firing beams intersecting the predetermined center of the prostate. Either three or five cross-firing portals are generally used, depending on the choice of the therapist and the calculated dose-distribution pattern for the individual patient. If three portals are used, one is anterior and two are posterior; if five portals are used, three are anterior and two are posterior. The midline is avoided on all posterior portals.



Figure—Technique for localization of the prostate prior to rotational or cross firing beam radiotherapy.

The portal size is a maximum of 8 by 8 cm at the center of rotation. According to the preference of the therapist, treatment may be directed through each of several portals daily. The common daily tumor dose is 180 rads to the 100% isodose contour. The total tumor dose is 6,000 to 6,500 rads to the 100% isodose contour is six to seven weeks of treatment. Split-course therapy is employed.

Details of the techniques used by the other reporting centers in delivering high-dosage irradiation to the prostate may be obtained by review of their published reports.[45-48]

Sequelae

A high percentage of patients undergoing high-dose irradiation to the prostate will have mild-to-moderate dysuria and diarrhea. These symptoms usually begin about 10 days after the initiation of therapy and, if no symptomatic treatment is given, persist for several weeks after the completion of therapy. In nearly all patients the symptoms are easily controlled. To date we have encountered no serious complications, such as rectal or bladder hemorrhage or rectal ulcer requiring surgical intervention. An occasional patient has required dilatation of the urethra after therapy. In general the symptoms are transient, mild, and easily controlled.

With many of the patients treated by radiation therapy, data on potency have not been collected before and after treatment. In Bagshaw and associates'[46] series of 18 patients on whom information was available 14 reported no change in potency whereas four noticed decreased potency. Two of George and associates'[47] patients were reportedly potent after treatment; information was not given on the remainder. Certainly the data pertaining to potency after treatment are important and should be gathered in future reports.

Efficacy of Treatment

All the investigators who have reported the use of supervoltage radiotherapy of prostatic carcinoma seem highly encouraged, and many centers are enthusiastic and frankly optimistic. Unfortunately, none of the series reported to date have been controlled series. Few of the patients have been traced for even five years; yet in prostatic cancer studies 10-year survival rates are required to provide a reliable guide for the efficacy of treatment. Furthermore, many of the patients have had prior surgical therapy or previous or continuing hormonal therapy. Some have even had previous instillations of ^{198}Au. At the present time it is impossible to give any meaningful survival figures or comparisons of one method of therapy (radiation versus surgery with or without hormones) with another.

Bagshaw and co-workers[46] summarized their experience by stating that 64 of 73 patients had striking alleviation of local symptoms and that 13 of 30 survived at least five years without evidence of local recurrence or distant metastasis. The five-year survival rate of the entire group, as computed by the actuarial method, was 54%.

As a result of their experience, Bagshaw and associates believe that survival rates after radiotherapy are comparable to rates after radical surgery and that there is less hazard to the patient and less disturbance of normal function. Del Regato[45] optimistically believes that certain types of radiotherapy will rapidly become the treatment of choice for all prostatic carcinomas (operable or inoperable) confined to the pelvis.

Work in Progress

A protocol study of carcinoma of the prostate has been undertaken at the Mayo Clinic in which there are five specific aims: (1) to determine the growth-rate pattern of prostatic carcinoma as related to age at onset, histologic grade, and clinical stage; (2) to determine the growth-rate pattern response to endocrine therapy, radical prostatectomy, and radiation therapy, as compared to untreated controls; (3) to determine the risks of the three treatment methods, as compared to the risk of the untreated cancer; (4) to determine the growth-rate pattern response to combinations of the three treatment methods, as compared to utilization of a single treatment method; and (5) to establish a reasonable clinical approach to the management of the patient who has not received conventional surgical, radiologic, or hormonal therapy.

In addition, because of the recent studies indicating the possibility of lymphogenous metastasis in clinical stages II and III prostatic carcinoma (probably about 25% and more than 90%, respectively), a study is planned incorporating lymphangiography before therapy (either surgery or irradiation or both). Lymphangiography should be a useful tool in assessing the extent of macroscopic disease and, consequently, an aid in determining the type and extent of the therapy employed.

Concluding Comments

The rationale of therapy is changing owing to recent advances in our knowledge of the pathophysiology of prostatic cancer. It has been shown that prostatic cancer is often multicentric in origin, may arise in any of the five lobes of the prostate, is usually subcapsular in origin, and involves lymphatic vessels more frequently and earlier than previously thought.

Staging and Grading

Knowledge of the natural history of untreated prostatic cancer is still incomplete but appears to follow a certain pattern. Occult or stage I cancer is almost always low grade and pursues an indolent course whether or not treatment is given. Stage II cancer (the localized nodule) is also usually low grade, but its natural history varies within the clinical stage, depending to some degree on histologic grade and microscopic extent of the tumor. Among the lower grade stage II cancers, some are lethal and others are indolent; there seems to be no way at present to distinguish between these. Little is known of the natural history of untreated stage II prostatic cancer. Stage III (local extension beyond the capsule) cancer is usually microscopically a high-grade maligancy, and less variation of its natural history is evident within the clinical stage. Untreated, it is more uniformly lethal. Stage IV represents metastatic prostatic cancer (usually high grade) and if untreated is uniformly lethal. Because of variations in the natural history, especially of stage II lesions, follow-up data on large groups of patients in well controlled series over long (10 to 15 years) periods are needed to elucidate the natural history of the lesions.

All the present forms of therapy for prostatic cancer have both risks and benefits. From the literature reviewed, the following conclusions may be drawn.

Stage I

In stage I, the so-called occult carcinoma of the usual low grade, the risks of radical surgery, hormone therapy, or high-dose radiation therapy probably outweigh the potential benefits to the patient. These patients do well with no further treatment and with regular follow-up. In the rare high-grade stage I carcinoma diffusely distributed throughout the prostate, treatment (either surgery or high-dose radiotherapy) appears indicated.

Stage II

In stage II cancer, treatment is indicated. Surgery will give good results if the lesion is low grade and microscopically confined to the prostate. Therefore the percentage of patients with stage I or II prostatic cancer considered operable is of utmost importance. Only 13% of all patients have such operable lesions. When further eliminations are made from this potentially operable group because of poor surgical risk, age, or refusal of surgery, the percentage of all patients with prostatic cancer who undergo radical surgery is about 5 to 7% in most institutions. Radiotherapy in this group may yet achieve good results.

Stage III

Stage III carcinoma is probably not amenable to radical prostatectomy unless prior radiation or hormonal therapy has produced favorable tumor shrinkage. Radiation therapy appers to be the treatment of choice if the tumor is confined to the pelvis. The preliminary results of similar techniques from other institutions, although inconclusive, are highly encouraging. Complications of radiation therapy have been few and relatively minor. Orchiectomy or estrogen use or both are suitable alternative therapeutic regimens. With our current knowledge of lymphatic spread, lymphangiography may be valuable in determining both the choice of therapy and the portal size, should megavoltage radiotherapy be the chosen modality. With radiotherapy in stage III disease, the portals should probably be large enough to include the pelvic lymph nodes. In patients not qualifying for surgery or radiotherapy, the nodule may be observed until it progresses or antiandrogenic therapy is started.

Stage IV

Patients with metastatic or stage IV disease are treated antiandrogenically. Radiation therapy of localized painful metastasis is valuable. Radioactive phosphorus should be used only as a last resort in widespread painful bony metastasis.

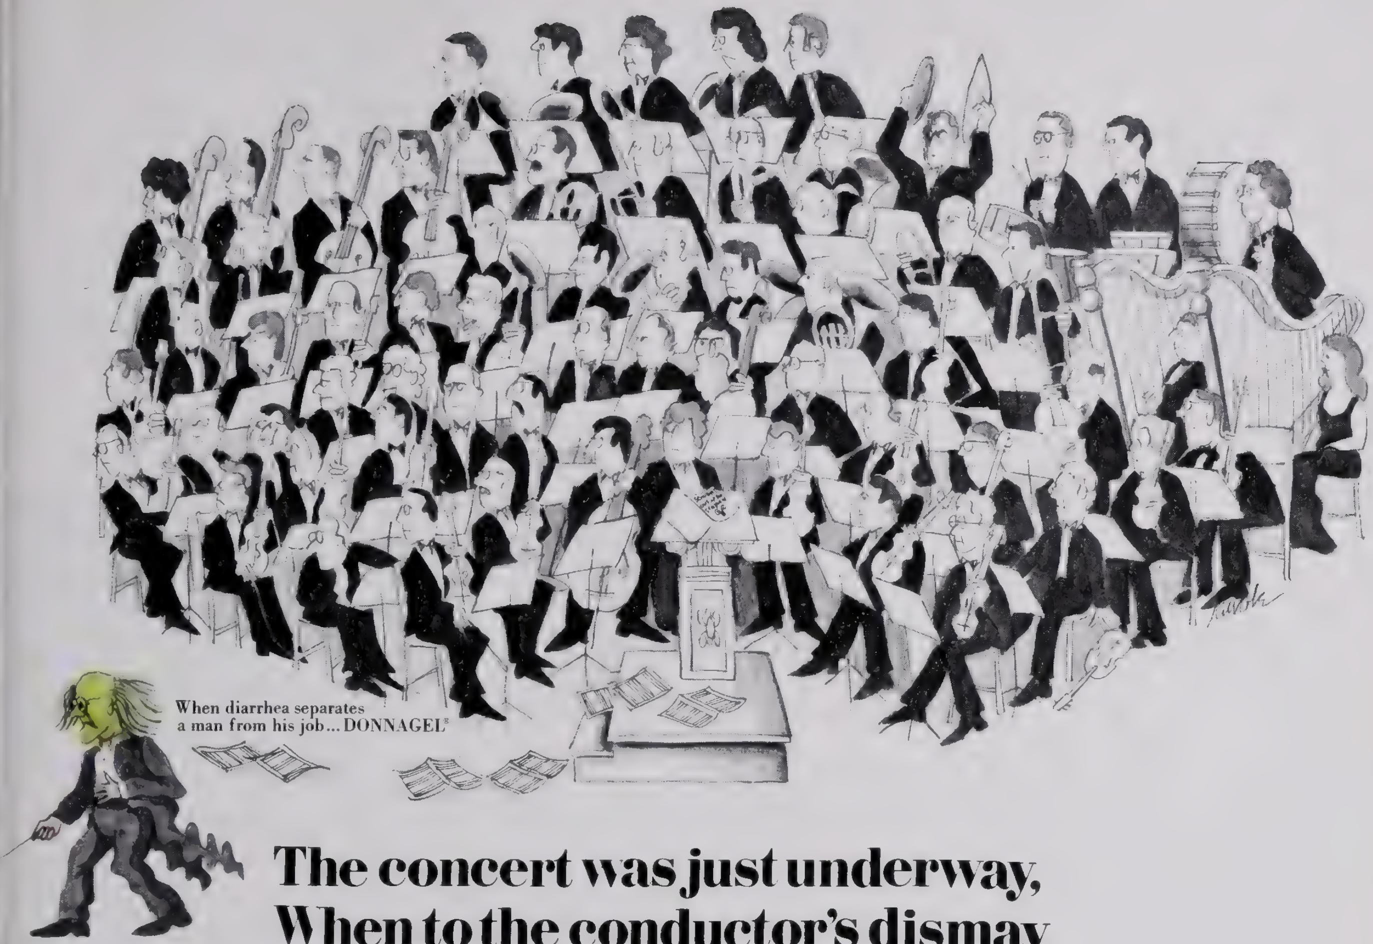
We are all miscarriages, but some miscarry at three months after conception and some at 100 years after birth.—Samuel Butler



When diarrhea separates
a man from his job... DONNAGEL®

The concert was just underway,
When to the conductor's dismay
Cramps and diarrhea,
Did so quickly appear,
The maestro no longer could stay.

Because diarrhea with cramping, nausea, and painful straining can strike at the most inopportune time, it takes a comprehensive agent to treat the total diarrheal syndrome and help get the patient back on the job. That's why so many physicians rely on Donnagel, especially during the fall and winter months when "flu" and viral gastroenteritis usually hit their peak.

Donnagel is much more than just a simple kaolin-pectin combination. It also contains the belladonna alkaloids to calm GI hypermotility and help relieve the distressing discomforts which so often accompany diarrhea. Certainly it's less expensive and more convenient than taking two medications. And the dosage is lower too. Available in the handy 4-oz. plastic bottle at pharmacies everywhere on your prescription or recommendation.

Donnagel
Schubert's Unfinished Symphony

For Diarrhea and its Discomforts

Donnagel®

Each fluid ounce contains: Kaolin, 6 Gm.; Pectin, 142.8 mg.; Hyoscyamine sulfate, 0.1037 mg.; Atropine sulfate, 0.0194 mg.; Hyoscine hydrobromide, 0.0065 mg.; Sodium benzoate (preservative), 60 mg.; Alcohol, 3.8%.

CLEAR THE TRACT!

THERE'S A ROBITUSSIN FOR EVERY COUGHING NEED

All the Robitussins contain gylceryl guaiacolate, an outstanding expectorant agent that greatly increases the output of lower respiratory tract fluid. Increased RTF volume exerts a demulcent effect on the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise.

For coughs of colds and "flu"
ROBITUSSIN®
Each 5 cc. contains:
Glyceryl guaiacolate . . 100.0 mg.
Alcohol, 3.5%

Non-narcotic for 6-8 hr. cough control
ROBITUSSIN-DM®
Each 5 cc. contains:
Glyceryl guaiacolate . . 100.0 mg.
Dextromethorphan hydrobromide . . . . 15.0 mg.
Alcohol, 1.4%

For unproductive allergic coughs
ROBITUSSIN A-C®
Each 5 cc. contains:
Glyceryl guaiacolate . . 100.0 mg.
Pheniramine maleate . . 7.5 mg.
Codeine phosphate . . . 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Clears sinuses and nasal stuffiness as it relieves cough
ROBITUSSIN-PE®
Each 5 cc. contains:
Glyceryl guaiacolate . . 100.0 mg.

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

INTERNIST—BROAD ELIGIBLE or Certified wanted to join two Internists, Radiologist, General Surgeon and EENT physician (all Mayo trained and Certified). Modern clinic building located in University city of Northeast Wisconsin having three fully equipped hospitals. For further information contact Administrator, Green Bay Clinic, 123 N. Military Ave., Green Bay, Wis. 54303.

WANTED: General Practitioner to join busy G. P. in ideal location. Partnership or salary with full hospital facilities. Contact M. J. Lindahl, M.D., Sherburn, Minnesota. Phone 507-764-4211 collect.

WANTED: General Practitioner or Internist, to join four man group in St. Paul. Partnership possible in one year. Dr. V. L. Sommerdorf, 1239 Payne Avenue, St. Paul, Minnesota 55101.

EXCELLENT OPPORTUNITY for General Practitioner and General Surgeon to join 4-man general practice group. Services of Radiologist immediately available. Liberal time off and post graduate allowances. Salary open with opportunity for early partnership. College town, population of 10,000, 30 miles from Minneapolis-St. Paul. Edward A. Jenkens, Mgr., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone number 425-5322.

OPPORTUNITY for career in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations. Give résumé. Write MINNESOTA MEDICINE—432, 375 Jackson, St. Paul 55101.

NEW EXPANDING OPPORTUNITIES for family physicians and physicians specializing in pediatrics, general surgery, internal medicine, urology, radiology, anaesthesiology; in medically-awakening community. Contemporary, automated, 105-bed, new hospital to be completed in the fall of 1970. Present hospital to be converted into long-term unit. Patient service area 50,000 people. Medical staff leading and supporting recruitment efforts. Excellent community location, forty miles equidistant to Milwaukee or Madison. Complete educational, cultural and recreational facilities. Possibility of new medical office building adjacent to new hospital. Immediate satisfaction in practice, income and family living. Special assistance if needed. Write or call Leo C. Bargielski, Administrator, Watertown Memorial Hospital, 1301 E. Main Street, Watertown, Wisconsin, 53094; telephone 414-261-4210 for more information.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

THE ADOLF GUNDERSEN MEDICAL FOUNDATION of La Crosse, Wisconsin, announces the establishment of a fully accredited three-year residency training program in Internal Medicine at Lutheran Hospital, La Crosse, Wisconsin. The hospital staff consists of a 65-man multiple specialty group with offices in a connecting modern clinic building. Eighteen fully qualified Internists serve as a nucleus of the teaching program. All staff men are full-time and salaried. This clinic-hospital complex serves as a referral center for a 100-mile radius. The hospital has a 375-bed facility. An intensive in-house training program is supported by weekly guest consultants. Stipend: $600 to $700 per month, plus housing and miscellaneous. Located in a progressive community with expanding university and private college. Population 50,000. Excellent school and recreation facilities. Applications being considered at all levels. Write: Edwin L. Overholt, M.D., Director, Medical Education and Research, Gundersen Clinic, Ltd., 1836 South Avenue, La Crosse, Wisconsin 54601.

GENERAL PRACTICE: INSTITUTIONAL: Desire a more regular life with regular hours, vacations, sick leave, time for attendance at meetings, etc? Consider working on a 60-bed medical service in a 350-bed psychiatric teaching hospital with a full-time Internist, several psychiatrists, part time surgeons and generalists at the Mental Health Institute, Cherokee, Iowa. Iowa licensure. Salary to $24,600 if eligible. Contact J. T. May, M.D., Superintendent.

EDUCATION PLUS: What midwestern high school of 170 boys currently has alumni at Harvard, Princeton, Swarthmore, M.I.T., McGill, London and Oxford (Rhodes Scholar), welcomes Americans, and produces great hockey teams? St. Johns-Ravenscourt School, Winnipeg 19, Manitoba. Headmaster: H. John P. Schaffter, M.A. (Cambridge), 204-453-3016.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

IMMEDIATE OPENING: Internist or General Practitioner to join six man multispecialty group in northeastern Wisconsin. Excellent professional opportunity to practice in a friendly community, only two actively practicing physicians (General Practitioners) in the community outside of our clinic. Salary commensurate with training and experience first year and then full partnership. Ideal, safe small city living for the family on scenic Lake Michigan with excellent fishing, boating and hunting. All this and still only 1½ hours drive to Milwaukee or 45 minutes to Green Bay or lovely Door County. For complete details contact Robert E. Myers, M.D., Garfield at 23rd, Two Rivers, Wisconsin 54241.

DOCTOR NEEDED in Int'l Falls, Minn. Excellent opportunity, partnership or private practice, medical office space available, new 65 bed hospital under construction. Excellent fishing, hunting and a winter wonderland. For details write or call collect: Medical Action Committee, Edwin M. Swanson, City Drug Store, Int'l Falls, Minn.

PHYSICIAN WANTED: G.P.—join young group of 4 GP's 4 day office week, high earnings, early partnership, immediate work load. Well equipped, newer clinic, fully accredited hospital, excellent practice conditions. Call collect 612-445-1305. Shakopee Medical Center. J. E. Ponterio, M.D., Shakopee, Minn.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

TEN MAN MULTISPECIALTY group needs an orthopedist, ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: General Practitioner to join Wisconsin practice 75 miles from the Twin Cities. Excellent JCAH hospital, extended-care facility, and office in resort area. $30,000 plus bonus first year. Partnership then available without investment. Write. MINNESOTA MEDICINE, 442, 375 Jackson, St. Paul 55101.

ASSOCIATE NEEDED to join 38 year old in General Practice 45 miles west of Minneapolis. Partner leaving mid-October. Medical clinic adjacent to 3 year accredited 27 bed hospital, both built in 1960. Terms negotiable. For further information contact A. J. Stifter, M.D., Winsted, Minnesota 612-485-2622 or 2230.

ST. PAUL—Spacious medical suite in new split-level building, part of a one block medical-dental complex adjacent to large shopping center. 1504 White Bear Avenue, 774-7144.

LARGE COMMUNITY HOSPITAL and medical center in the southwest needs a full time director of internal medicine service. Hospital has over 500 beds, internships and eight approved residency programs including internal medicine. Member of the Council of Teaching Hospitals of AAMC. Director of internal medicine is responsible for all activities related to internal medicine within the medical center. Annual compensation, $40,000. Write: MINNESOTA MEDICINE—444, 375 Jackson, St. Paul 55101.

FLORIDA OPPORTUNITY! Needed January 1, 1970 and July 1, 1970, retiring physicians to work in the Emergency and Outpatient Department, Naples, Florida. Fee-for-service, 24 hours a week. Florida license. Ideal environment. Would consider M.D. awaiting residency or armed service assignment for 40 hour week and same conditions. Write: C. N. Cooper, M.D., 350 Seventh St. North, Naples, Florida 33940.

WANTED: 2 full time physicians for Mankato State College Health service. Salary open and usual fringe benefits. Active, interesting, and rewarding position for those who like young people. Summer duty is light. Call or write R. G. Hankerson, M.D., Health Service, Mankato State College, Mankato, Minn. (507) 389-2726.

A miracle: an event described by those to whom it was told by men who did not see it.—Elbert Hubbard

"All Interns are Alike"

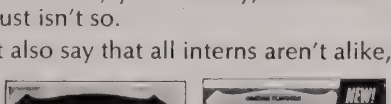
It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.



Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic /antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering Librium (chlordiazepoxide hydrochloride) to known addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards. As with all anticholinergic drugs, an inhibiting effect on lactation may occur.

PRECAUTIONS: In elderly and debilitated, limit dosage to smallest effective amount to preclude development of ataxia, oversedation or confusion (not more than two capsules per day initially; increase gradually as needed and toler-

ated). Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

ADVERSE REACTIONS: No side effects or manifestations not seen with either compound alone have been reported with Librax. When chlordiazepoxide hydrochloride is used alone, drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

No place for beginners

Terramycin®
(oxytetracycline)

An infection of rapid onset requiring prompt attention. Teenage girl with chills, fever, abdominal pain, backache and nausea. Frequent and urgent urination with burning. On examination—tenderness over kidney. Blood count and urinalysis confirm the diagnosis: acute pyelonephritis. Treatment is initiated with Terramycin. Within a few days of follow-up therapy, the patient is markedly improved. The pretreatment urine culture shows a strain of *E. coli* highly susceptible to Terramycin.

Experience has shown that Terramycin offers special advantages in treating urinary tract infections when strains of causative bacteria are susceptible. Broad-spectrum coverage unaffected by penicillinase. Effective tissue levels to help reach foci of infection in renal parenchyma. High urine levels—excreted by kidney in *active* form.

With Terramycin, you have the assurance that comes with choosing an agent physicians have depended on for over 18 years. In difficult as well as routine cases, when tests reveal susceptible organisms, consider Terramycin. One of the world's most widely used broad-spectrums.

Contraindicated: In individuals hypersensitive to oxytetracycline.

Warnings: Reduce usual oral dosage and consider antibiotic serum level determinations in patients with impaired renal function.

Use of oxytetracycline during the last trimester of pregnancy, neonatal period and early childhood may cause discoloration of developing teeth. This effect occurs mostly during long-term use of the drug, but it has also been observed in usual short-treatment courses.

During treatment with tetracyclines, individuals susceptible to photodynamic reactions should avoid direct sunlight; if such reactions occur, discontinue therapy.

Note: With oxytetracycline, phototoxicity is unknown and photoallergy very rare.

Precautions: Use of broad-spectrum antibiotics occasionally may result in overgrowth of nonsusceptible organisms. Where such infections occur, discontinue oxytetracycline and institute specific therapy. Increased intracranial pressure in infants is a possibility. Symptoms disappear upon discontinuation of therapy.

Adverse Reactions: Nausea, diarrhea, glossitis, stomatitis, proctitis, vaginitis and dermatitis, as well as reactions of an allergic nature, may occur but are rare.

Supply:* Terramycin Capsules: oxytetracycline HCl, 250 mg. and 125 mg. Terramycin Syrup: calcium oxytetracycline, 125 mg. per 5 cc. Terramycin Pediatric Drops: calcium oxytetracycline, 100 mg. per cc.

*All potencies listed are in terms of the standard, oxytetracycline.

Pfizer LABORATORIES DIVISION
New York, N.Y. 10017

For elderly patients
in need of a mild tranquilizer
consider **Tybatran®**
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

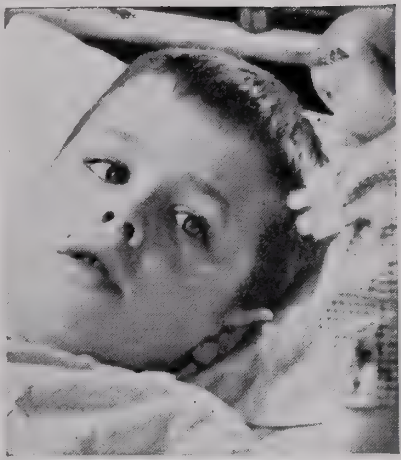
Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

A. H. Robins Company, Richmond, Va. 23220

A·H·ROBINS



Save him from

RHEUMATIC FEVER

Here are two ways:

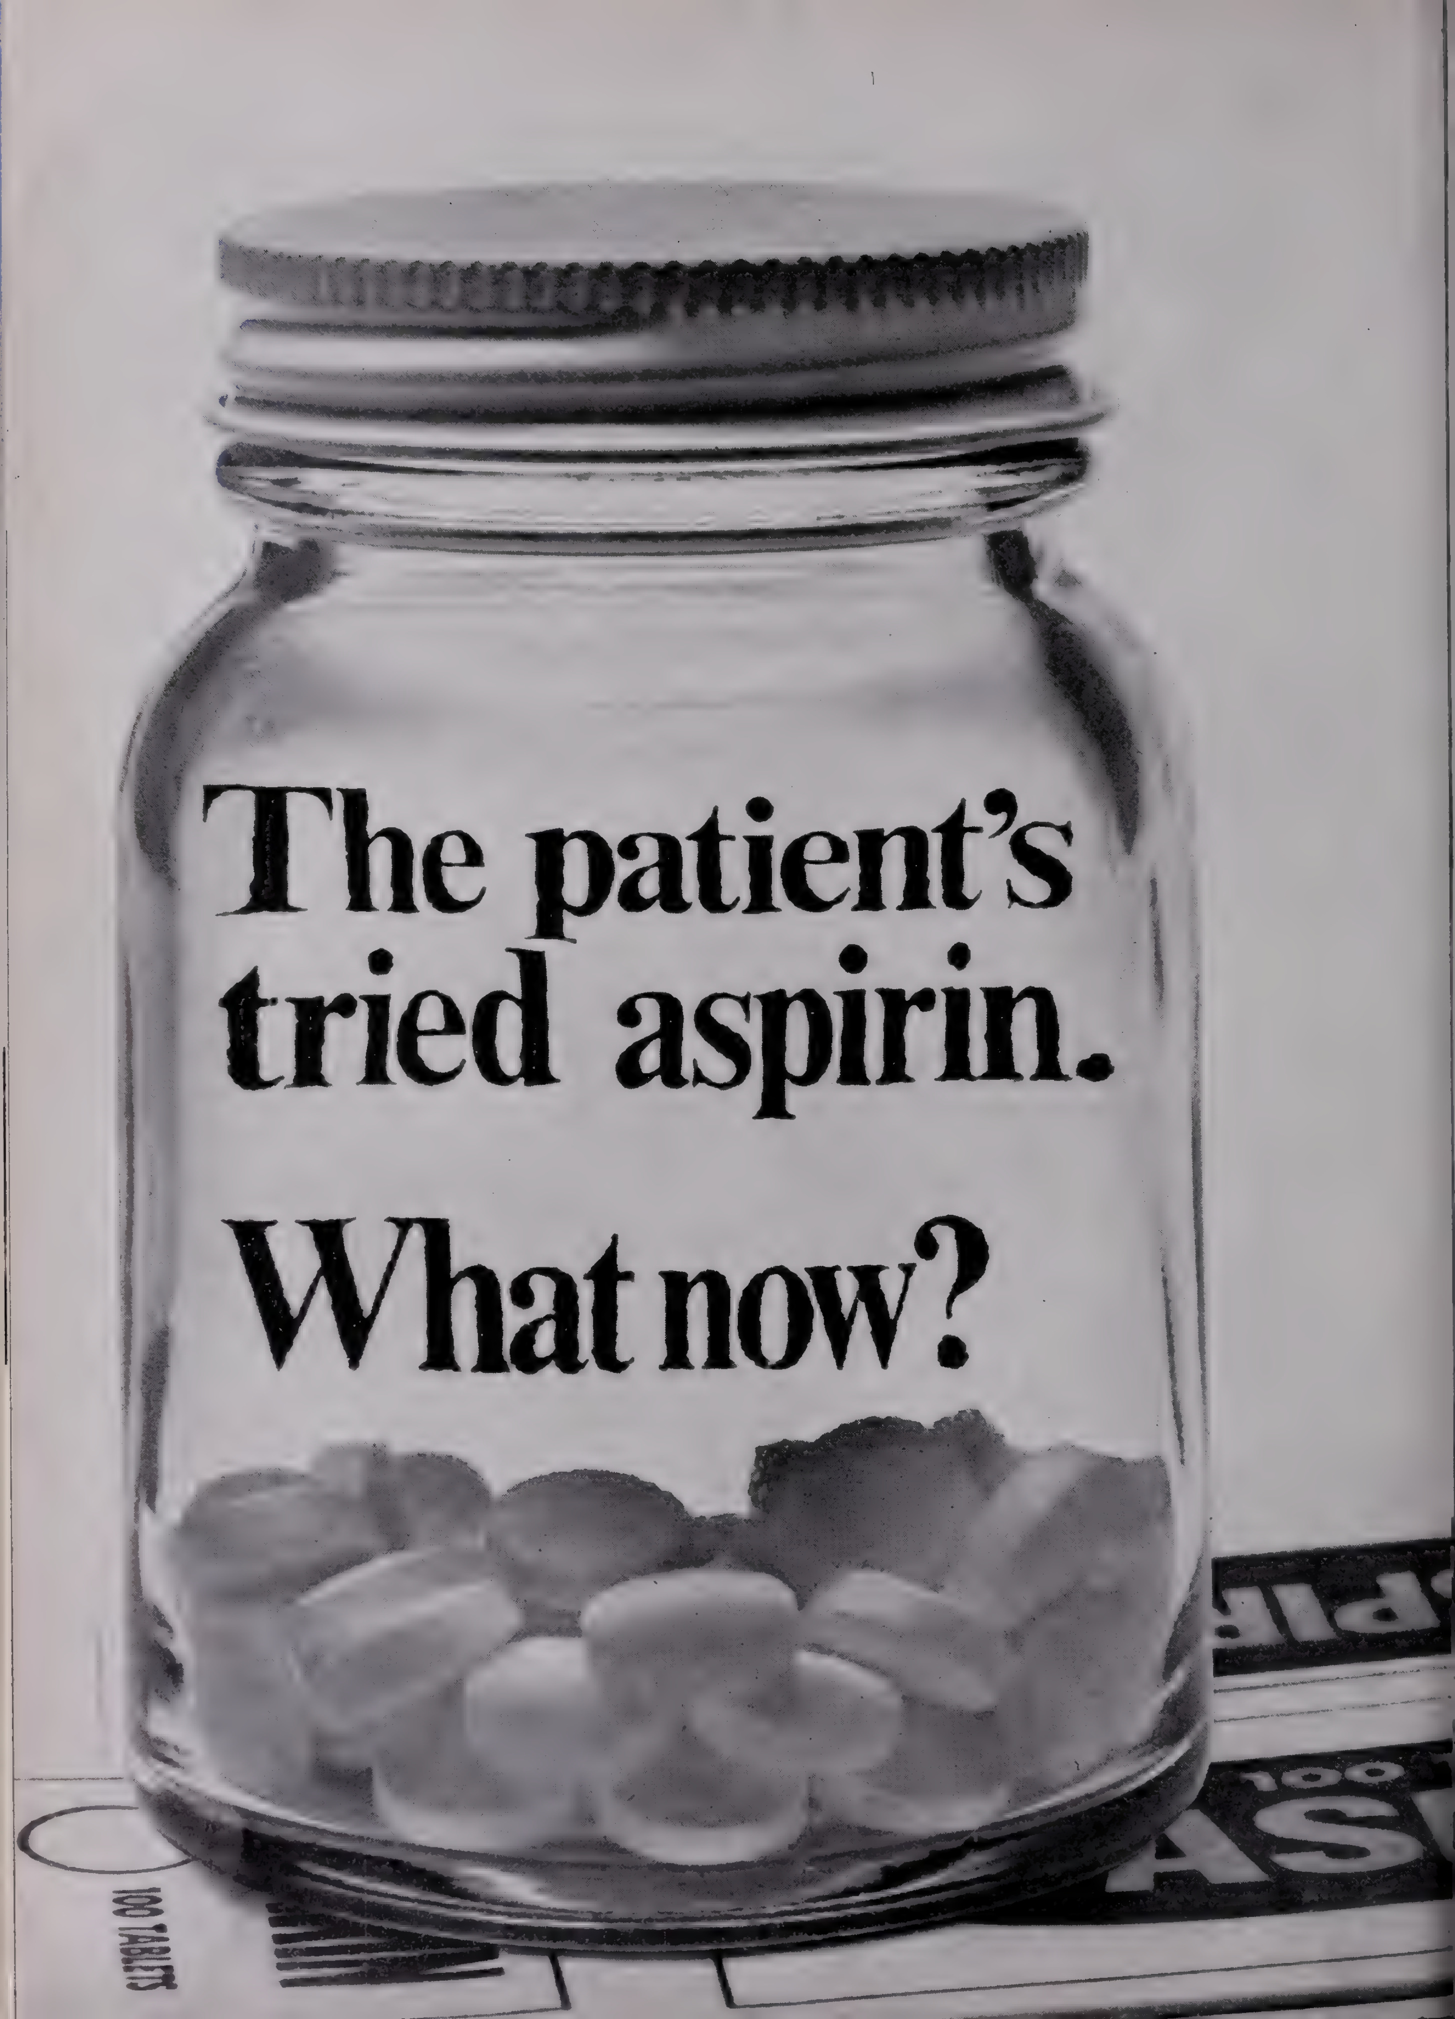
1. If your child has a bad sore throat, don't wait – it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...

so more will live

HEART FUND



The patient's tried aspirin.
What now?
100 TABLETS

There's a good chance your patient needs more than a non-prescription analgesic for pain relief. Especially after self-medication has failed.

Because continuing, increased pain and discomfort may in part be a reflection of anxiety, Equagesic is worthy of consideration. In a single, non-narcotic preparation, it helps relieve pain . . . *and* associated anxiety and tension.

Tablets

Equagesic®

(meprobamate and ethoheptazine citrate with aspirin) Wyeth

IN BRIEF

Contraindications: History of sensitivity or severe intolerance to aspirin, meprobamate or ethoheptazine citrate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore, it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics—has resulted in dependence or habituation. Withdraw gradually after prolonged excessive dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance, with resultant slowed reactions and impaired judgment and coordination. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, patients should not operate machinery or drive. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously and in small amounts to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with gastric lavage and appropriate symptomatic therapy (CNS stimulants and pressor amines as indicated). Two instances of accidental or intentional significant overdosage with ethoheptazine and aspirin have been reported. These were accompanied by CNS depression (drowsiness and lightheadedness) but resulted in uneventful recovery. On basis of pharmacologic data, CNS stimulation could be anticipated, with nausea, vomiting and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]).

Adverse Reactions: Ethoheptazine and aspirin may cause nausea with or without vomiting and epigastric distress in a small percentage of patients. Dizziness is rare at recommended dosage. Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses. Such patients may have had no previous contact with meprobamate and may or may not have an allergic history. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, discontinue meprobamate; do not reinstitute. Severe reactions, observed very rarely, include fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. These cases should be treated symptomatically including, when indicated, such medication as epinephrine, antihistamine and possibly hydrocortisone. A few cases of leukopenia, usually transient, have been reported on continuous use. Rarely, aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported, almost always in presence of known toxic agents.

Overdosage: See precautions section for management of overdosage.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

If she asks what you think of babyScott

The next page will help you answer.

Introducing the babyScott diaper system. Designed with infants, mothers, and physicians in mind.

Two-part system offers clinical advantages as well as convenience and efficiency.

The diaper panty: it takes anatomy into consideration. The babyScott diaper panty is specifically designed to hold the babyScott disposable diaper securely, yet without constriction. The panty fits low in front to avoid pressure on the umbilicus. And high on the legs so it won't chafe, bind or interfere with mobility.

Four different sizes and multi-position snaps help assure good fit and comfort. "Safety" pins, which can always pose a threat, are completely unnecessary.

All portions of the panty that come in contact with the infant's skin are covered with soft, quick-drying cloth.

Essentially non-absorbent, the babyScott panty can be thoroughly and rapidly washed, rinsed and dried.

The disposable diaper: it takes sensitive skin into consideration. The disposable diaper, itself, is thick, fluffy and soft. Its layers of highly absorbent cellulose fluff are covered by a web-like liner, which is both permeable and relatively hydrophilic to help keep infants drier.

Doubly thick for extra absorption in front, the diaper fans out bucket-seat fashion in the back for wide coverage. The babyScott diaper thus provides excellent protection while minimizing bunching and consequent irritation. On those occasions when double diapers are used for extra protection comfort is still maintained.

With babyScott, each diaper comes fresh and clean out of the pack. It's used only once, then flushed away or otherwise disposed of.

No soap, detergent or bleach residues. No opportunity for cross contamination from the diaper.

A frequently changed infant is a healthier, happier infant.
And the babyScott diaper system is so easy to use, it will be used.

babyScott®
the pinless diaper

When disease is ruled out and psychic tension is implicated

Valium® (diazepam)

helps relax the patient and relieve his somatic symptoms

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.
